Moser and von Pirquet⁶ later showed that the serum of horses immunized with scarlet fever streptococci did not produce agglutination of all streptococci cultivated from scarlet fever blood.

Weaver⁷ made an exhaustive study of agglutination of streptococci with human serum. He came to the conclusion that the agglutination of streptococci from cases of scarlet fever was in no way specific and could be of no value as a means of diagnosis. He found that

some of the streptococci from scarlet fever were agglutinated by almost all scarlatinal serums, others only by some, and many not at all. Streptococci from scarlet fever were agglutinated also by serum from cases of lobar pneumonia and erysipelas at about the same dilutions as by scarlatinal serums, and the same was true with the few specimens of typhoid blood and puerperal fever serum examined. As the experiments were made before hemolytic and green-producing streptococci were differentiated, it is possible that some of Weaver's strains were not hemolytic and may even have been pneumococci.

Rosswald and Schick⁸ found that Moser's anti-streptococcus serum (serum of horse immunized with scarlet fever streptococci) agglutinated many, but not all, strains of streptococci from scarlet fever patients. They isolated a streptococcus from a case of surgical scarlet fever, which was agglutinated by Moser's serum in high dilution. They concluded that the streptococci from scarlet fever that were not agglutinated by the immune horse serum belonged to a different group from those that were agglutinated.

Ruediger⁹ immunized sheep with different strains of streptococci, and found that many strains of hemolytic streptococci from scarlet fever were agglutinated by the serum of the sheep immunized with a streptococcus isolated from a scarlet fever throat, but not by the serum of sheep immunized with a hemolytic streptococcus isolated from a phlegmon of the leg. Of the eleven strains obtained from scarlet fever patients, three were not agglutinated by the scarlet fever sheep serum. Two of these organisms had each been passed through more than fifteen rabbits; the third was obtained from the suppurating cervical glands of a very mild case of scarlet fever which had appeared at the end of the fourth week. He also obtained agglutination of hemolytic streptococci isolated from erysipelas and tonsillitis in as high dilutions of the serum as in some of the scarlet fever strains.

In my study¹⁰ of the opsonic index in scarlet fever I found that the variations in the index for the scarlatinal hemolytic streptococcus even in mild cases indicated that practically from the first the scarlet fever patient is subject to a definite streptococcus infection. In the beginning of the attack the streptococco-opsonic index in the majority of cases was below normal; as the acute symptoms subsided the index rose above normal, to which it soon returned; definite local streptococcal complications were inaugurated by a depression in the streptococco-opsonic index, which rose again as improvement took place. These changes were specific for the hemolytic streptococcus, no changes occurring with staphylococci, pneumococci or *Streptococcus viridans*. Similar results were obtained by Banks.¹¹

Recently Nakayama¹² studied agglutination of hemolytic streptococci with immune rabbit serum with considerable similarity in the results with various strains of streptococci from scarlet fever; but no distinct line could be drawn between streptococci obtained from the throat and from ordinary suppurative processes. His absorption experiments did not give decisive results; the agglutinins and opsonins did not always run parallel in the serum of the same rabbit, and it did not seem possible to classify streptococci by means of opsonins.

It has been found that the opsonin reaction may serve as a means by which green-producing streptococci may be reliably differentiated (poliomyelitis,¹³ measles,¹⁴ rubella,¹⁴ influenza¹⁵). Therefore the experiments outlined below were made to study once more the question of the specificity of the hemolytic streptococcus in scarlet fever, especially in regard to opsonification, as agglutination of streptococci is uncertain.

A sheep was immunized with a hemolytic streptococcus, isolated from the throat of a severe acute case of scarlet fever. The sheep was inoculated intravenously weekly, at first with killed cultures, later with small numbers of living cocci. Opsonins were produced after the first injection, agglutinins after the sixth. The cocci were grown on goat blood agar twenty-four hours and suspended in physiologic sodium chlorid solution. Normal sheep leukocytes, collected in 0.2 per cent. sodium citrate solution and washed once in physiologic sodium chlorid solution, were used in the experiments. The serum, normal and immune, was heated for one-half hour at 56 C. to remove the thermolabile element, and then diluted to determine the point of opsonic extinction. The mixtures of serum, leukocytes and coccal suspension, equal parts, were incubated twenty-five minutes, smears stained with carbolthionin, fifty polymorphonuclear leukocytes counted, and the number of cells taking part in phagocytosis noted. Spontaneous agglutination of streptococci did not interfere with the opsonic determinations.

The agglutination experiments proved very troublesome. Plain neutral broth (Weaver⁷), calcium carbonate broth (Ruediger⁹), blood glucose broth (Hamilton and Havens¹⁶) and phosphate broth (Dochez, Avery and Lancefield¹⁷), all were found unsatisfactory on account of spontaneous clumping of the organisms. As I had previously observed that streptococci grow more diffusely in ascitic dextrose broth than in plain or dextrose broth alone, this medium was used. One part of ascitic fluid was added to four parts of 0.2 per cent. dextrose broth p_H 7.4. The cultures were incubated twenty-four hours, centrifuged, the supernatant fluid removed, and the organisms were washed once or twice with plain meat infusion broth p_H 7.8 and finally suspended in this medium. In the tests, the serum dilutions were made with plain broth, the dilutions running from 1:5 to 1:1,000, and an equal part of bacterial suspension was added to each tube of diluted serum, and the mixtures were incubated for one hour and fifteen minutes at 55 C., and then left at room temperature for three hours. A tube containing suspended cocci in broth but without serum and one with cocci in normal sheep serum diluted from 1:5 to 1:100 or higher were included in each agglutination test. As a rule the results were clear at the end of the incubation period. The immunizing streptococcus, however, was always included in each experiment to serve as a standard. Four strains were found to agglutinate spontaneously and therefore could not be tested.

The following hemolytic streptococci were used: 27 strains isolated early in the attack of scarlet fever,

2 before the appearance of the rash (throat 20, otitis media 1, mastoid 1, finger 2, empyema 2, gland 1); 9 from the throat and 2 from ears during convalescence; 1 from wound from possible case of scarlet fever; 3 from blood, cerebrospinal fluid and knee of suspected case of scarlet fever; 26 strains were isolated from cases which were not scarlatinal in origin—normal throats 5; influenza 5, empyema 2, sputum 2, lung 1; measles 2, throat, ear; erysipelas 3; diphtheria, 2; mastoid, 1; otitis media, 1; chronic rhinitis, 1; meningitis, 1; acute tonsillitis, 1; horse pneumonia, 1; acute sinusitis, 1; blood in lethargic encephalitis, 1.

All of these strains but one produced a wide zone of hemolysis (from 2 to 4 mm.) on goat blood agar plates, after twenty-four hours' incubation. The streptococcus that produced a narrow zone of hemolysis was isolated from the ear of a scarlet fever patient during the sixth week of the disease. The size of the colonies varied somewhat, but were generally small, round and smooth. The strains from erysipelas, influenza and lethargic encephalitis produced, as a rule, larger, flatter colonies than the others. With a few exceptions the streptococci fermented lactose and salicin, but not mannite or inulin, and hence would be classed as *Streptococcus pyogenes* (Holman¹⁸). Two scarlet fever strains, one from the finger and one from an empyema, fermented lactose and mannite but not inulin and salicin (*Streptococcus hemolyticus* one); one diphtheria streptococcus originally an anaerobe fermented salicin but not lactose, mannite or inulin (*Streptococcus equi*).

Of the hemolytic streptococci isolated from the throat and the complicating lesions of early cases of scarlet fever, all gave marked phagocytosis with the immune sheep serum except the two mannite fermenters, the point of opsonic extinction being from 1:30 to 1:1,500, 1:150 being the point at which phagocytosis ceased for the majority of the strains. The contrast between the specimens with normal and immune serum was very striking on account of there being little or no phagocytosis of these scarlatinal streptococci in normal heated sheep serum when first isolated.

Three scarlet fever streptococcus strains agglutinated spontaneously and could not be tested. One streptococcus from a gland, though opsonized, was not agglutinated by the immune sheep serum. The other twenty-three scarlet fever strains were all agglutinated by the immune serum at a dilution of from 1:50 to 1:2,000, 1:500 being the dilution at which the majority of the cocci ceased to agglutinate. Only an occasional strain agglutinated at 1:5 with normal sheep serum.

The hemolytic streptococcus from the finger and the one from empyema, both mannite fermenters, as well as the strains from otitis media of two scarlet fever cases in the fourth and sixth weeks, and from the wound, blood, cerebrospinal fluid and knee of two suspected cases of scarlet fever, were neither opsonized nor agglutinated by the immune sheep serum. The two mannite fermenters agglutinated spontaneously and could not be used for agglutination tests.

None of the hemolytic streptococci isolated from the throat late in scarlet fever, except in the instances to be noted, and none from sources other than scarlet fever, were opsonized by the immune sheep serum in dilutions higher than by normal serum; and none of these cultures were agglutinated by either normal or

immune serum. Here it may be said that one reason why the results of these experiments indicate a greater specificity than those of certain other observers is probably the heating of the serum, which destroys the labile factors that participate in the action of normal serum.

Hemolytic streptococci obtained from the throats of nine patients during convalescence from scarlet fever, one during the second, the others during the third and fourth weeks, were not agglutinated by the immune serum and not opsonized in higher dilutions than with normal serum. It is noteworthy that cultures of four of these patients had been taken previously and hemolytic streptococci obtained which reacted positively with the immune serum, but that during the third week the cultures of two of them gave only a few colonies of hemolytic streptococci, which in the one case tested did not react with the immune sheep serum. Cultures from both of these patients showed large numbers of hemolytic streptococci during the fourth week, which were opsonized and agglutinated in high dilutions with the immune serum. Neither patient complained of sore throat, but the tonsils were slightly redder than normal. From one patient hemolytic streptococci were isolated one week later, which were not opsonized or agglutinated by the immune serum. Further studies of scarlet fever patients along these lines must be made. The results so far indicate that the hemolytic streptococci isolated from the throat at the onset of the attack of scarlet fever are immunologically different from most of those obtained during convalescence, and that some of the hemolytic streptococci in complicating lesions may differ immunologically from the streptococci in the acute stage of scarlet fever. These results also suggest that immune sheep serum may be helpful in diagnosing suspected cases of scarlet fever and in determining the length of quarantine for patients with purulent discharges.

ABSORPTION EXPERIMENTS

Absorption experiments were made to determine whether the agglutinins and opsonins could be absorbed by the heterologous streptococci, from scarlet fever and from other sources, as thoroughly as by the immunizing coccus. Immune serum was therefore treated with the homologous and with two other hemolytic streptococci, one from a scarlatinal otitis, the other from erysipelas. The otitis streptococcus was opsonified and agglutinated by the untreated immune sheep serum. Killed centrifuged organisms were suspended in the immune serum, which then was incubated two hours and refrigerated for twenty-four hours, and finally centrifuged, the supernatant serum being removed. This process was repeated three times, when the serum was found no longer to opsonify or agglutinate the immunizing coccus. Absorption with the two scarlet fever streptococcus strains removed the opsonins and agglutinins for the nineteen scarlet fever streptococcus strains tested, but absorption with the erysipelas streptococcus failed to remove the opsonins and agglutinins for the scarlet fever streptococci. These results indicate clearly that the hemolytic streptococci that prevail in the throat in the acute stages of scarlet fever form a group immunologically closely related and apparently peculiar for scarlet fever.

CONCLUSIONS

The serum of sheep immunized with hemolytic streptococci from the throat in the acute stage of scarlet fever has been found to contain opsonins and agglu-

tinins for the hemolytic streptococci that prevail in the throat and complicating lesions early in this disease, but not for hemolytic streptococci from other sources, such as erysipelas, mastoiditis, measles, influenza, diphtheria and the normal throat. The results of absorption tests also indicate that the hemolytic streptococcus from scarlet fever forms a distinct group, scarlatinal streptococci removing the opsonins and agglutinins for these cocci, while absorption with a hemolytic streptococcus from erysipelas has no such effect.

These results suggest that the hemolytic streptococci of scarlet fever form a distinct group from the immunologic point of view. Possibly the serum produced with this scarlatinal streptococcus group may prove of use in the diagnosis and treatment of scarlet fever, and eventually, perhaps, in determining the length of infectivity.

Clinical Notes, Suggestions, and New Instruments

A CASE OF UNUSUAL URINARY CALCULI

AUGUSTUS HARRIS, M.D., BROOKLYN

The stones shown in the accompanying illustration were removed from the bladder of a patient suffering from prostatism, and their unusual form prompted me to present the case.

Urinary calculi, about half their actual size.

REPORT OF CASE

A rather feeble man, aged 75, was admitted to the urologic service at the Kings County Hospital, Feb. 1, 1920, suffering with an attack of acute retention of urine. He stated that an ambulance surgeon from another hospital had tried for two hours to pass instruments into the bladder, without success.

On admission, the patient appeared weak and was suffering severe pain. The pulse was irregular and of poor volume. Two members of the house staff tried to catheterize but failed. There was moderate bleeding from the urethra, and apparently a false passage had been made. The prostate was markedly enlarged, smooth, and fairly hard. On account of the patient's general condition, an emergency suprapubic one-step drainage operation was immediately decided on.

Stovain spinal anesthesia was employed. I opened the bladder, and about 16 ounces of bloody urine were evacuated. On exploration, the bladder was found hypertrophied and trabeculated. No large pockets were discovered. Lying free on the floor of the bladder behind the prostate were five stones, four of which are depicted in the illustration. These were removed, and the bladder and tissues closed about the drainage tube in the usual manner.

The stones were light brown, smooth, and of light weight. They were shiny on the surface, as if varnished. The main body of each was round, and from it projected spines with smooth, rounded ends. They resembled rather closely a handful of jackstones, with which little girls play.

An analysis of one of the stones disclosed lamination on cross section. Microscopically, there were uric acid crystals and amorphous urates. Chemically, there was a mixture of uric acid, urates, xanthin and carbonates. The stones in the illustration are just about half their actual size. It would be interesting to know how these calculi took on this curious form.

The urine was alkaline in reaction.

306 Park Place.

PROCEEDINGS OF THE NEW ORLEANS SESSION

MINUTES OF THE SEVENTY-FIRST ANNUAL SESSION OF THE AMERICAN
MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, APRIL 26-30, 1920

(Continued from page 1328)

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, APRIL 28—AFTERNOON

The section was called to order at 2 o'clock by the chairman, Dr. James S. McLester, Birmingham, Ala.

Dr. McLester read the chairman's address, entitled "Clearness in Medical Speech."

Dr. Henry S. Plummer, Rochester, Minn., read a paper on "The Clinical Interpretation of Basal Metabolic Rate Estimations." Discussed by Drs. Emil Goetsch, Brooklyn; Leonard G. Rowntree, Minneapolis; Nelson W. Janney, Santa Barbara, Calif., and H. S. Plummer, Rochester, Minn.

Dr. Frank Billings, Chicago, nominated for Honorary Fellowship Sir Humphry D. Rolleston, London, England. Seconded and carried.

Drs. Rollin T. Woodyatt and William D. Sansum, Chicago, presented a paper on "The Nature of Fever." Discussed by Drs. W. S. Thayer, Baltimore, Alexander Lambert, New York; L. G. Rowntree, Minneapolis; Francis M. Pottenger, Monrovia, Calif., and R. T. Woodyatt, Chicago.

Dr. George Dock, St. Louis, nominated for Honorary Fellowship Dr. Twaho Tsuchiya, Tokyo, Japan. Seconded and carried.

Dr. Stewart R. Roberts, Atlanta, Ga., read a paper on "Types and Treatment of Pellagra." Discussed by Drs. Marvin L. Graves, Galveston, Texas; Allen Eustis, New Orleans; Henry S. Plummer, Rochester, Minn.; George Dock, St. Louis; W. K. Sheddin, Columbia, Tenn., and S. R. Roberts, Atlanta, Ga.

Dr. Bryce W. Fontaine, Memphis, Tenn., read a paper on "The End-Results of Focal Infections." Discussed by Drs. Frank Billings, Chicago; Joseph H. Pratt, Boston; Frank B. Wynn, Indianapolis; W. S. Thayer, Baltimore; Leon L. Solomon, Louisville, Ky.; Carleton Dederer, Bay City, Mich., and B. W. Fontaine, Memphis, Tenn.

Dr. Charles F. Hoover, Cleveland, read a paper on "The Clinical Diagnosis of Obstruction of the Hepatic Veins." Discussed by Sir Humphry Rolleston, London, England; Dr. Frank B. Wynn, Indianapolis, and Dr. C. F. Hoover, Indianapolis.

Dr. William Gerry Morgan, Washington, D. C., read a paper on "Phlebectasis of the Diaphragmatic Area and of the Lower Thoracic and Upper Abdominal Regions." Discussed by Drs. J. Russell Verbrycke, Jr., Washington, D. C.; Charles F. Hoover, Cleveland; Louis J. Genella, New Orleans; Frank Billings, Chicago; William S. Thayer, Baltimore, and W. G. Morgan, Washington, D. C.

THURSDAY, APRIL 29—AFTERNOON

The section was called to order at 2 o'clock by the chairman.

Sir Humphry D. Rolleston, London, England, read a paper on "Changes in the Clinical Types of Disease." No discussion.

Dr. U. J. W. Peters, Birmingham, Ala., read a paper on "Abscess of the Lung." Discussed by Drs. Charles F. Hoover, Cleveland; O. M. Gilbert, Boulder, Colo.; C. J. Fishman, Oklahoma City; A. C. Eustis, New Orleans, and U. J. W. Peters, Birmingham, Ala.

Dr. George Dock, St. Louis, read a paper on "Oxycephaly: Its Occurrence in Negroes." Discussed by Dr. Stewart R. Roberts, Atlanta, Ga.

Drs. Howard F. West and Joseph H. Pratt, Boston, presented a paper on "Clinical Experience with a Standardized Dried Aqueous Extract of Digitalis." Discussed by Drs. G. Canby Robinson, Nashville, Tenn., and C. F. Wahrer, Fort Madison, Iowa.

Dr. John Peter Schneider, Minneapolis, read a paper on "A Study of the Bile Pigments in Pernicious Anemia." Discussed by Drs. Leonard G. Rowntree, Minneapolis; F. J. Hirschboeck, Duluth, Minn.; Llewellyn Sale, St. Louis, and F. P. Schneider, Minneapolis.

Dr. Douglas VanderHoof, Richmond, Va., read a paper on "Spondylitis and Abdominal Pain." Discussed by Drs. Gustave Roussy, Paris, France (translated by Dr. William S. Thayer, Baltimore); Sir Humphry D. Rolleston, London, England, and Douglas VanderHoof, Richmond, Va.

Dr. W. L. Bierring, Des Moines, Iowa, nominated for Honorary Fellowship Dr. Gustave Roussy, Paris, France. Seconded and carried.

Dr. Eugene S. Kilgore, San Francisco, read a paper on "The Influence of Quantitative Methods in the Advance of Clinical Medicine." Discussed by Drs. Henry A. Christian, Boston, and E. S. Kilgore, San Francisco.

FRIDAY, APRIL 30—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman.

Dr. Charles Spencer Williamson, Chicago, read a paper on "Gout: A Clinical Study of One Hundred and Sixteen Cases." Discussed by Dr. Walter L. Bierring, Des Moines, Iowa; Sir Humphry D. Rolleston, London, England; Alexander Lambert, New York, and C. S. Williamson, Chicago.

The chairman announced that Dr. G. Canby Robinson had resigned as secretary of the section for reasons which were beyond his control.

It was moved, seconded and carried that Dr. Robinson's resignation be accepted with regret.

The following officers were elected: chairman, Dr. Henry S. Plummer, Rochester, Minn.; vice chairman, Dr. G. Canby Robinson, Nashville, Tenn.; secretary, Nellis B. Foster, New York; delegate, Dr. James S. McLester, Birmingham, Ala.

Dr. James E. Paullin, Atlanta, Ga., read a paper on "Renal Glycosuria." Discussed by Drs. Nelson W. Janney, Santa Barbara, Calif.; Albert A. Hornor, Jr., Boston; Allan Eustis, New Orleans, and J. E. Paullin, Atlanta, Ga.

Drs. Nelson W. Janney, Santa Barbara, Calif., and Robert R. Newell, San Francisco, presented a paper on "The Treatment of Diabetes Complicated by Pulmonary Tuberculosis." Discussed by Drs. Francis M. Pottenger, Monrovia, Calif.; F. M. Allen, New York; William C. Voorsanger, San Francisco; L. J. Genella, New Orleans, and N. W. Janney, Santa Barbara, Calif.

Dr. William Engelbach, St. Louis, read a paper on "Arterial Hypertension Associated with Endocrine Dyscrasia." Discussed by Dr. Francis M. Pottenger, Monrovia, Calif.; Prof. Gustave Roussy, Paris, France, and Drs. C. J. Fishman, Oklahoma City; F. M. Allen, New York; William S. Thayer, Baltimore, and William Engelbach, St. Louis.

Dr. Loyd Thompson, Hot Springs, Ark., read a paper on "Syphilis of the Kidney." Discussed by Drs. John Witherpoon, Nashville, Tenn.; William H. Mercur, Pittsburgh, and J. B. McElroy, Memphis, Tenn.

Dr. William P. St. Lawrence, New York, read a paper on "The Effect of Tonsillectomy on the Recurrence of Acute

Rheumatic Fever and Chorea in Children." Discussed by Drs. Lewis A. Conner, New York; Alexander Lambert, New York, and W. P. St. Lawrence, New York.

Dr. W. R. Taylor, Fort Recovery, Ohio, presented the following resolution:

Resolved, That the members of the American Medical Association return their heartfelt thanks to the civil officers of the state of Louisiana, to those of the city of New Orleans, to the officers of the state medical society of this splendid state, and especially to the members of the Orleans Parish Medical Societies, and to all of the people of this city, rich in the history of our common country, for the magnificent manner in which they have instructed and entertained us.

On motion, duly seconded and carried, the foregoing resolution was adopted by the section.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Dean D. Lewis, Chicago.

The following papers were read as a symposium on the "Thyroid":

Dr. James T. Mason, Seattle: "One Hundred Goiter Operations: Mistakes in Retrospect."

Dr. Frank H. Lahey, Boston: "Diagnosis and Management of Intrathoracic Thyroid Growths."

Dr. Joseph R. Eastman, Indianapolis: "Advantages of Local Anesthesia in Thyroid Operations."

Dr. Willard Bartlett, St. Louis: "Technic of Thyroidectomy."

These four papers were discussed by Drs. Henry S. Plummer, Rochester, Minn.; Emil Goetsch, Brooklyn; Edward G. Jones, Atlanta, Ga.; A. J. Ochsner, Chicago; Andre Crotti, Columbus, Ohio; M. L. Harris, Chicago; G. W. Crile, Cleveland; James T. Mason, Seattle; Frank H. Lahey, Boston; Joseph R. Eastman, Indianapolis, and Willard Bartlett, St. Louis.

Dr. Joseph C. Bloodgood, Baltimore, read a paper on "Chronic Cystic Mastitis." Discussed by Drs. William C. MacCarty, Rochester, Minn., and Joseph C. Bloodgood, Baltimore.

Dr. Alfred W. Adson, Rochester, Minn., read a paper on "Brain Abscess."

Dr. George J. Heuer, Baltimore, read a paper on "Surgical Experiences with an Intracranial Approach to Chiasmal Lesions."

These two papers were discussed by Drs. H. R. Donaldson, Atlanta, Ga.; G. M. Dorrance, Philadelphia; Alfred W. Adson, Rochester, Minn., and George J. Heuer, Baltimore.

Dr. Francis Le S. Reder, St. Louis, read a paper on "Hemangioma and Lymphangioma: Their Response to the Injection of Boiling Water." Discussed by Drs. Rudolph Matas, New Orleans; Vilray P. Blair, St. Louis, and Francis Le S. Reder, St. Louis.

THURSDAY, APRIL 29—MORNING

The meeting was called to order by the chairman.

Dr. Dean D. Lewis, Chicago, read the chairman's address.

Dr. Alexander Primrose, Toronto, read a paper on "Squamous-Cell Carcinoma of the Kidney." Discussed by Drs. A. D. Bevan, Chicago; W. J. Mayo, Rochester, Minn.; J. J. Gilbride, Philadelphia; A. J. Ochsner, Chicago, and Alexander Primrose, Toronto.

The chairman appointed Drs. Wallace I. Terry, San Francisco, and Willard Bartlett, St. Louis, to serve on the executive committee in the absence of Drs. W. D. Haggard, Nashville, Tenn., and E. Starr Judd, Rochester, Minn.

Dr. William A. Downes, New York, read a paper on "Congenital Hypertrophic Pyloric Stenosis in Infants: Review of One Hundred and Seventy-five Cases in Which the Fredet-Rammstedt Operation Was Performed." Discussed by Drs. Dean D. Lewis, Chicago; Roland Hill, St. Louis; A. A. Strauss, Chicago; L. T. Le Wald, New York; A. D. Bevan, Chicago; J. L. Ransohoff, Cincinnati; W. A. Downes, New York, and A. D. Bevan, Chicago.

Dr. Wallace I. Terry, San Francisco, read a paper on "Ulcer of the Jejunum Following Gastro-Enterostomy." Discussed by Drs. J. Shelton Horsley, Richmond, Va.; W. J. Mayo, Rochester, Minn.; A. J. Ochsner, Chicago; A. A. Strauss, Chicago, and W. I. Terry, San Francisco.

Dr. A. D. Bevan, Chicago, read a paper on "Surgery of Cancer of the Large Intestine."

Dr. G. W. Crile, Cleveland, read a paper on "Operation for Carcinoma of the Rectum."

These two papers were discussed by Drs. Daniel F. Jones, Boston, and W. J. Mayo, Rochester, Minn.

At the request of the chairman the session was addressed by the following distinguished guests: Col. H. J. Waring, Royal College of Surgeons, London; Dr. E. E. Desmarest, professor of surgery, University of Paris, and Dr. Jules Voncken, Liège, Belgium.

Drs. Arthur Stein and William H. Stewart, New York, presented a paper on "Roentgenologic Experience with Pneumoperitoneum." Discussed by Drs. George E. Pfahler, Philadelphia; B. H. Orndoff, Chicago, and W. H. Stewart, New York.

Dr. Walter Lathrop, Hazleton, Pa., read a paper on "Ether Oil Colonic Anesthesia." Discussed by Drs. James T. Gwathmey, New York; Alexander Primrose, Toronto; J. Shelton Horsley, Richmond, Va.; G. W. Crile, Cleveland, and Walter Lathrop, Hazleton, Pa.

FRIDAY, APRIL 30—MORNING

The meeting was called to order at 9 o'clock by the vice chairman, Malvern B. Clopton, St. Louis.

The following officers were elected: Chairman, Dr. George P. Muller, Philadelphia; vice chairman, Dr. Edward Clarence Moore, Los Angeles; secretary, Dr. Urban Maes, New Orleans; delegate, Dr. R. P. Sullivan, New York; alternate, Dr. D. F. Jones, Boston.

Dr. Evarts A. Graham, St. Louis, read a paper on "Importance of the 'Vital Capacity' in Thoracic Surgery."

Dr. John L. Yates, Milwaukee, read a paper on "Prevention and Treatment of Pleurisy."

Dr. Carl Eggers, New York, read a paper on "Observations on the Relative Value of the Various Operative Procedures Employed in Acute Empyema."

These three papers were discussed by Drs. Alexander Lambert, New York; Martin B. Tinker, Ithaca, N. Y.; Arvine E. Mazing, Indianapolis; James F. Mitchell, Washington, D. C.; Moses Behrend, Philadelphia; C. D. Lockwood, Pasadena, Calif.; George J. Heuer, Baltimore; T. T. Thomas, Philadelphia; Carl A. Hedblom, Rochester, Minn.; H. M. Richter, Chicago; Rosalie Slaughter Morton, New York; John B. Haeblerlin, Chicago; E. A. Graham, St. Louis; John L. Yates, Milwaukee, and Carl Eggers, New York.

Dr. Addison G. Brenizer, Charlotte, N. C., read a paper on "The Use of Bone and Fascia Grafts in the Reconstruction of Bones and Joints."

Dr. Paul B. Magnuson, Chicago, read a paper on "Mechanic Stability of Fractures Following Operation."

These two papers were discussed by Drs. Harry M. Sherman, San Francisco; E. W. Ryerson, Chicago; W. R. Cubbins, Chicago; T. Turner Thomas, Philadelphia; Paul A. McIlhenny, New Orleans; A. G. Brenizer, Charlotte, N. C., and Paul B. Magnuson, Chicago.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

WEDNESDAY, APRIL 28—AFTERNOON

The chairman, Dr. Reuben Peterson, Ann Arbor, Mich., called the meeting to order at 2 o'clock.

Dr. Reuben Peterson, Ann Arbor, Mich., read the chairman's address entitled "The Future of Obstetrics and Gynecology as a Specialty."

Dr. Arthur H. Curtis, Chicago, read a paper on "Chronic Leukorrhea: Its Pathology and Treatment." Discussed by Drs. Francis Le S. Reder, St. Louis; T. J. Watkins, Chicago; Peter B. Salatch, New Orleans, and Arthur H. Curtis, Chicago.

Dr. William J. Mayo, Rochester, Minn., read a paper on "Conservation of the Menstrual Function." Discussed by Drs. C. Jeff Miller, New Orleans; John O. Polak, Brooklyn; Robert T. Morris, New York; A. J. Ochsner, Chicago, and W. J. Mayo, Rochester, Minn.

Dr. Emil Novak, Baltimore, read a paper on "Relation of Hyperplasia of the Endometrium to So-Called Functional Uterine Hemorrhage." Discussed by Drs. Lucius E. Burch, Nashville, Tenn.; Henry P. Newman, San Diego, Calif., and Emil Novak, Baltimore.

Dr. John O. Polak, Brooklyn, read a paper on "A Plea for Total Hysterectomy in the Operative Treatment of Fibroid Tumors of the Uterus in Parous Women." Discussed by Drs. E. E. Montgomery, Philadelphia; Albert Goldspohn, Chicago; William Kohlmann, New Orleans; A. C. Scott, Temple, Texas, and John O. Polak, Brooklyn.

Dr. William W. Grant, Denver, read a paper on "Hernia of the Ovary." Discussed by Drs. George H. Lee, Galveston, Texas; Albert Goldspohn, Chicago, and William W. Grant, Denver.

The chairman announced that the following distinguished physicians were attending the Association session: Col. H. J. Waring, Royal College of Surgeons, England; Dr. E. E. Demarest, professor of surgery, University of Paris, and Dr. Jules Voncken, Liège, Belgium. On motion by Dr. Arthur H. Curtis, Chicago, duly seconded and carried, these gentlemen were elected to honorary fellowship and invited to participate in the proceedings.

Dr. John M. Maury, Memphis, Tenn., read a paper on "Results of the Exposure of Animal Ovaries to the Rays of Radium." Discussed by Drs. Henry Schmitz, Chicago, and John M. Maury, Memphis, Tenn.

THURSDAY, APRIL 29—AFTERNOON

The chairman called the meeting to order at 2 o'clock.

Dr. Mathias J. Seifert, Chicago, read a paper on "Abnormal Lactation." Discussed by Dr. William Kohlmann, New Orleans.

Dr. Isador C. Rubin, New York, read a paper on "Intra-Uterine Insufflation of Oxygen (Artificial Pneumoperitoneum) for the Determination of Potency of the Fallopian Tubes in Cases of Sterility." Discussed by Drs. J. O. Polak, Brooklyn, and Isador C. Rubin, New York.

Dr. Edward L. King, New Orleans, read a paper on "The Policy of Noninterference in the Treatment of Postabortive and Puerperal Infections." Discussed by Drs. J. O. Polak, Brooklyn, and Edward L. King, New Orleans.

Dr. James M. Mason, Birmingham, Ala., read a paper on "The Management of Acute Appendicitis in the Later Weeks of Pregnancy: Report of Case Treated by Cesarean Section and Appendectomy." Discussed by Drs. Arthur H. Curtis, Chicago; Francis Le S. Reder, St. Louis; David Ross, Indianapolis, and James M. Mason, Birmingham, Ala.

The chairman announced that Dr. T. J. Watkins, Chicago, who had been appointed a substitute on the Executive Committee, had been obliged to leave, and therefore he would appoint Dr. Arthur H. Curtis, Chicago, on the Executive Committee.

FRIDAY, APRIL 30—AFTERNOON

The chairman called the meeting to order at 2 o'clock.

The following officers were elected: chairman, Dr. John O. Polak, Brooklyn; vice chairman, Dr. Lucius E. Burch, Nashville, Tenn.; secretary, Dr. Sidney A. Chalfant, Pittsburgh; delegate, Dr. Edward Reynolds, Boston; alternate, Dr. S. M. D. Clark, New Orleans.

The paper of Dr. Carroll W. Allen, New Orleans, on "An Operation for Pruritus of the Vulva and Anus," was read by Dr. E. Denegre Martin, New Orleans. Discussed by Dr. Denegre Martin, New Orleans.

Dr. Richard R. Smith, Grand Rapids, Mich., read a paper on "Prolapse of the Urethra in the Female." Discussed by Drs. S. M. D. Clark, New Orleans; F. F. Lawrence, Columbus, Ohio; Arthur H. Curtis, Chicago, and Richard R. Smith, Grand Rapids, Mich.

Dr. John J. Gilbride, Philadelphia, read a paper on "Cysts of the Pancreas." Discussed by Drs. A. C. Scott, Temple,

Texas; Moses Behrend, Philadelphia, and Marcell Hartwig, Los Angeles.

Dr. Moses Behrend, Philadelphia, read a paper on "An Improved Technic for Cholecystectomy Based on an Anatomic Study." Discussed by Drs. A. C. Wood, Philadelphia; J. B. Haeberlin, Chicago; M. J. Seifert, Chicago; J. J. Gilbride, Philadelphia; E. P. Quain, Bismarck, N. D.; H. M. Richter, Chicago, and Moses Behrend, Philadelphia.

Dr. Edgar P. Hogan, Birmingham, Ala., read a paper on "Appendicitis Caused by Amebae Dysenteriae: Postoperative Perforation of an Amebic Ulcer of the Cecum." Discussed by Drs. J. B. Haeberlin, Chicago, and Edgar P. Hogan, Birmingham, Ala.

SECTION ON OPHTHALMOLOGY

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order at 9:15 by the chairman, Dr. Allen Greenwood, Boston.

Dr. Allen Greenwood, Boston, read the chairman's address, entitled "Postgraduate Ophthalmology."

Dr. James Bordley, Jr., Baltimore, read a paper on "Optic Nerve Disturbances in Diseases of the Posterior Nasal Sinuses."

Dr. Edward C. Ellett, Memphis, Tenn., read a paper on "Optic Neuritis Associated with Disease of the Nasal Sinuses."

These two papers were discussed by Drs. George E. de Schweinitz, Philadelphia; Lee M. Francis, Buffalo; William C. Posey, Philadelphia; Harry S. Gradle, Chicago; Samuel G. Higgins, Milwaukee; Hiram Woods, Baltimore; Harold Bailey, Springfield, Mo.; H. B. Lemere, Omaha; Herbert Moulton, Fort Smith, Ark., and Nelson M. Black, Milwaukee.

Dr. J. Herbert Claiborne, New York, read a paper on "Ocular Symptoms in Exophthalmic Goiter." Discussed by Drs. Albert E. Bulson, Jr., Fort Wayne, Ind.; W. H. Wilder, Chicago; Edward Jackson, Denver, and J. Herbert Claiborne, New York.

Drs. Walter B. Lancaster, Boston; Francis L. Burnett, Boston, and Louis H. Gaus, Boston, presented a paper on "Mercurochrome-220: A Clinical and Laboratory Report on Its Use in Ophthalmology." Discussed by Drs. J. Herbert Claiborne, New York; George S. Derby, Boston; Hiram Woods, Baltimore; Benjamin F. Travis, Chattanooga, Tenn., and Walter B. Lancaster, Boston.

THURSDAY, APRIL 29—MORNING

The meeting was called to order at 9:10 by the chairman.

Dr. J. Herbert Claiborne, New York, presented a pair of bifocal cataract glasses.

Sylvester J. Beach, Augusta, Maine, presented a rapid clinical perimeter.

Dr. J. Ellis Jennings, St. Louis, presented a new lantern for the detection of color blindness.

Dr. Lawrence T. Post, St. Louis, presented a thermaphor devised by Dr. William E. Shahan, St. Louis.

Dr. E. A. Robin, New Orleans, presented a colored woman, aged 31, whose vision had been failing for eight years, and asked for a diagnosis.

Dr. Sidney L. Olsho, Philadelphia, presented a new trial frame with more delicately adjusted tilting temples for use in spectacle and eye-glass fitting.

Dr. Edward J. Curran, Kansas City, Mo., read a paper on "Peripheral Iridectomy in Chronic Glaucoma." Discussed by Drs. William Zentmayer, Philadelphia; Harold Bailey, Springfield, Mo.; Meyer Wiener, St. Louis, and Edward J. Curran, Kansas City, Mo.

Drs. Lawrence Post, St. Louis, and William E. Shahan, St. Louis, presented a paper on "Thermaphor Studies in Glaucoma." Discussed by Drs. John O. McReynolds, Dallas, Texas; George S. Derby, Boston, and Lawrence Post, St. Louis.

Dr. Harry H. Stark, El Paso, Texas, read a paper on "Diagnosis of Chronic Intra-Ocular Tuberculosis." Discussed by Drs. William C. Finnoff, Denver; Walter R. Parker, Detroit; Edward Jackson, Denver; Harry S. Gradle,

Chicago; Hiram Woods, Baltimore; George S. Derby, Boston, Harry H. Stark, El Paso, Texas.

Dr. Arthur J. Bedell, Albany, N. Y., read a paper on "Ethylhydrocuprein in Diseases of the Eye." Discussed by Drs. Harry S. Gradle, Chicago; Edward C. Ellett, Memphis, Tenn.; James M. Patton, Omaha; William Zentmayer, Philadelphia; Lewis H. Taylor, Wilkes-Barre, Pa.; Harry H. Stark, El Paso, Texas; Lee M. Francis, Buffalo; William C. Fimoff, Denver; Allen Greenwood, Boston, and Arthur J. Bedell, Albany, N. Y.

Dr. Marcus Feingold, New Orleans, read a paper on "Peripheral Communicating Vessels Between Retina and Choroid, with Remarks on Fold of the Inner Limiting Membrane in Certain Cases of Chorioretinitis." Discussed by Drs. Edward Jackson, Denver; Edward C. Ellett, Memphis, Tenn., and Charles A. Bahn, New Orleans.

FRIDAY, APRIL 30—MORNING

The meeting was called to order at 9:15 by the chairman.

Dr. Allen Greenwood made a verbal report for the Committee on Preparation of Compensation Tables, and asked that this committee be dissolved. It was moved by Dr. C. D. Wescott, Chicago, that the present committee be dissolved and a new committee appointed by the chairman. Motion seconded and carried.

Dr. Edward Jackson, Denver, read the report of the Committee on Standardization of Undergraduate Teaching of Ophthalmology. It was moved by Dr. C. D. Wescott, Chicago, that this report be accepted and the committee discharged, with the thanks of the section. Motion seconded and carried.

Dr. George S. Derby, Boston, read a letter from the Committee on Conferring the Knapp Medal, stating that the committee had decided that it was unable to confer the medal this year, as the papers presented at the last meeting of the section did not reach the required standard. This report was accepted without vote.

Dr. Lucien Howe, Buffalo, made a report for the Committee on the Study of Ocular Muscles. Moved by Dr. Robert H. T. Mann, Texarkana, Ark., that this report be accepted and the committee continued. Motion seconded and carried.

Dr. Lucien Howe, Buffalo, made a report for the Committee on the Prevention of Hereditary Blindness. Moved by Dr. Walter R. Parker, Detroit, that the report be accepted and the committee continued. Motion seconded and carried.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., made a report for the Committee for the Study of Local Anesthesia. Moved by Dr. Robert H. T. Mann, Texarkana, Ark., that the report be accepted and the committee continued. Motion seconded and carried.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., read the report of the Committee on the Knapp Testimonial. Moved by Dr. C. D. Wescott, Chicago, that the report be accepted and the committee continued. Motion seconded and carried.

Dr. William H. Wilder, Chicago, read a report for the Committee on International Congress of Ophthalmologists. Moved by Dr. C. D. Wescott, Chicago, that the report be accepted and the committee continued. Motion seconded and carried.

Dr. Edward Jackson, Denver, read the report of the Committee on Ophthalmologic Examinations. Moved by Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., that the report be accepted and the committee continued. Motion seconded and carried.

Dr. William C. Posey, Philadelphia, read the report of the Committee on the Ultraviolet and Visible Transmission of Eye-Protective Glasses. Moved by Dr. W. B. Lancaster, Boston, that the report be adopted, and the committee continued, and asked to make a statement showing under what conditions such lenses are wisely prescribed by ophthalmologists; also that this report be printed in the transactions. Motion seconded and carried.

Dr. Henry D. Bruns, New Orleans, offered a resolution asking that this section devise ways and means for the correct diagnosis of follicular trachoma. Moved by Dr. Edward C. Ellett, Memphis, Tenn., that this resolution be

referred to a committee of three, to be appointed by the chairman, which committee shall investigate and report at the next session of this section. Motion seconded and carried.

Dr. George S. Derby, Boston, then read the standing rules and regulations governing the section.

Dr. William Zentmayer, Philadelphia, presented the following report for the executive committee:

The executive committee recommends the adoption of the rules as read with the following amendments:

The time allowed for the presentation of a paper before the section shall be limited to ten minutes. The speaker appointed to open the discussion shall be allowed ten minutes, with the exception that the time may be extended by unanimous consent of those present when the speaker is an invited guest of the section. The Executive Committee further recommends:

That our delegate to the House of Delegates be instructed to inform the House that it is the sense of the Executive Committee that the three-session plan should be given a further trial to determine whether or not it should be permanently adopted.

The Executive Committee further recommends that the section inform the Trustees that at the present time the allowance made to the secretary is insufficient to pay the expenses incurred and that they be requested to increase the allowance to meet the present needs of the secretary.

The executive committee recommends for nomination the following officers for this section: chairman, James Bordley, Jr., Baltimore; vice chairman, Marcus Feingold, New Orleans; delegate, Lee M. Francis, Buffalo, and member examining board, Albert E. Bulson, Jr., Fort Wayne, Ind.

Moved by Dr. Nelson M. Black, Milwaukee, that the secretary be instructed to incorporate into the rules of this section such of these rules as are not at present in force. Motion seconded and carried.

Moved by Dr. Henry D. Bruns, New Orleans, that the paragraph of the report relating to the instructions to the delegate to the House be adopted. Motion seconded and carried.

Moved by Dr. William C. Posey, Philadelphia, that the secretary be instructed to cast the unanimous ballot of the section for the officers named in the report. Motion seconded and carried.

Moved by Dr. Albert E. Bulson, Jr., Fort Wayne, Ind., that it is the sense of the Section on Ophthalmology that discussions of papers shall be submitted to the discussants for correction before they are published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION; also that THE JOURNAL shall print the minutes of the executive session, after they have been submitted to the secretary of the section for revision. Motion seconded and carried.

Moved that Drs. Walter R. Parker, Detroit; Lee M. Francis, Buffalo, and Lewis H. Taylor, Wilkes-Barre, Pa., be made the Committee on Awards. Motion seconded and carried.

Moved by Dr. William Zentmayer, Philadelphia, that a committee be appointed to draw up suitable resolutions relative to the death of Dr. Samuel D. Risley, Philadelphia. Motion seconded and carried. The chairman appointed on this committee: Drs. George E. de Schweinitz, Philadelphia; William Zentmayer, Philadelphia, and G. Oram Ring, Philadelphia.

Executive session adjourned.

Dr. Lucien Howe, Buffalo, read a paper on "The Coefficient of Thermal Conductivity of Eye and Orbit Measured with Cold Applications." Discussed by Drs. Edward Jackson, Denver; Walter B. Lancaster, Boston, and Lucien Howe, Buffalo.

The new chairman, Dr. James Bordley, Jr., presided during the rest of the session.

Dr. William L. Benedict, Rochester, Minn., read a paper on "Early Diagnosis of Pituitary Tumor with Ocular Phenomena." Discussed by Drs. F. Phinizy Calhoun, Atlanta, Ga.; George E. de Schweinitz, Philadelphia; Alfred W. Adson, Rochester, Minn.; Walter R. Parker, Detroit; Allen Greenwood, Boston; George S. Derby, Boston; William Zentmayer, Philadelphia, and William L. Benedict, Rochester, Minn.

Dr. Herbert Moulton, Fort Smith, Ark., read a paper on "Sympathetic Ophthalmia: Report of Four Cases in Which the Condition Was Treated with Large Doses of Sodium Salicylate." Discussed by Drs. James M. Patton, Omaha;

John A. Donovan, Butte, Mont.; E. H. Frederick Frisch, Atlantic City, N. J.; Hugh M. Lokey, Atlanta, Ga., and Herbert Moulton, Fort Smith, Ark.

Drs. Meyer Wiener, St. Louis, and William E. Sauer, St. Louis, presented a paper on "A New Operation for the Relief of Dacryocystitis Through the Nasal Route." Discussed by Drs. William H. Wilder, Chicago; Walter B. Lancaster, Boston; William L. Benedict, Rochester, Minn.; William C. Posey, Philadelphia; Louis D. Green, San Francisco; Earl Whedon, Sheridan, Wyo., and Meyer Wiener, St. Louis.

Dr. John M. Wheeler, New York, read a paper on "Restoration of the Margin and Neighboring Portion of the Eyelid by a Free Graft from the Lower Part of the Eyebrow and the Skin Directly Below It." Discussed by Drs. Nelson M. Black, Milwaukee; William C. Posey, Philadelphia; Gaylord C. Hall, Louisville, Ky., and John M. Wheeler, New York.

The chairman appointed these committees:

Committee to investigate regarding the diagnosis of follicular trachoma: Drs. Henry D. Bruns, New Orleans; E. A. Robin, New Orleans, and Edward C. Ellett, Memphis, Tenn.

Committee on Compensation: Drs. Nelson M. Black, Milwaukee; Harry S. Gradle, Chicago, and Albert C. Snell, Rochester, N. Y.

SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

WEDNESDAY, APRIL 28—AFTERNOON

The meeting was called to order at 2:15 by the chairman, Dr. Joseph C. Beck, Chicago.

The chairman announced that in the absence of Dr. Greenfield Sluder, St. Louis, Dr. George M. Coates, Philadelphia, would act as a member of the Executive Committee.

Dr. Joseph C. Beck, Chicago, read the chairman's address, entitled "The Future of Otolaryngology."

It was moved by Dr. William B. Chamberlin, Cleveland, that the presentation of reports as well as papers be limited to fifteen minutes. Seconded and carried.

Dr. Ferris N. Smith, Grand Rapids, Mich., read a paper on "Plastic Surgery: Its Relation to the Otolaryngologist."

Dr. Millard R. Arbuckle, East St. Louis, Ill., read a paper on "Plastic Surgery of the Face." Discussed by Drs. George M. Coates, Philadelphia; George M. Dorrance, Philadelphia; Austin A. Hayden, Chicago; Ferris N. Smith, Grand Rapids, Mich., and Millard F. Arbuckle, East St. Louis, Ill.

Dr. Gordon B. New, Rochester, Minn., read a paper on "Mixed Tumors of the Throat, Mouth and Face." Discussed by Drs. Lee W. Dean, Iowa City; Wendell C. Phillips, New York; John F. Barnhill, Indianapolis; T. E. Carmody, Denver, and Gordon B. New, Rochester, Minn.

Dr. John F. Barnhill, Indianapolis, read a paper on "Thyroid Surgery, Especially as Related to Laryngology." Discussed by Drs. Emil Mayer, New York; Norval H. Pierce, Chicago; Joseph C. Beck, Chicago; T. E. Carmody, Denver, and John F. Barnhill, Indianapolis.

Dr. Robert Sonnenschein, Chicago, read a paper on "The Use and Possible Abuse of Radium in the Treatment of Malignant Tumors of the Nose and Throat." Discussed by Drs. William B. Chamberlin, Cleveland; Cullen F. Welty, San Francisco; Joseph D. Heitger, Louisville, Ky.; G. E. Pfahler, Philadelphia; S. G. Higgins, Milwaukee; Albert F. Tyler, Omaha, and Robert Sonnenschein, Chicago.

Dr. Richmond McKinney, Memphis, Tenn., read a paper on "Misleading Symptoms and Roentgen-Ray Findings in Suspected Mastoid Abscess." Discussed by Drs. Francis P. Emerson, Boston; Cullen F. Welty, San Francisco; G. H. Mundt, Chicago; William B. Chamberlin, Cleveland; E. Lee Myers, St. Louis, and Richmond McKinney, Memphis, Tenn.

THURSDAY, APRIL 29—AFTERNOON

The meeting was called to order at 2:10 by the chairman.

Dr. Joseph D. Heitger, Louisville, Ky., read a paper on "Present Status of Neurotology from the Borderline Standpoint." Discussed by Drs. Harold L. Lillie, Rochester, Minn.; George W. MacKenzie, Philadelphia; Lee W. Dean, Iowa City; Julius Grinker, Chicago, and Joseph D. Heitger, Louisville, Ky.

Dr. Eugene R. Carpenter, Dallas, Texas, read a paper on "Intracranial Lesions Involving the Auditory Vestibular Apparatus." Discussed by Drs. Isaac W. Jones, Los Angeles; Harold I. Lillie, Rochester, Minn.; Tom A. Williams, Washington, D. C.; George W. MacKenzie, Philadelphia; Julius Grinker, Chicago, and Eugene R. Carpenter, Dallas, Texas.

Dr. George W. MacKenzie, Philadelphia, read a paper on "Neurolabyrinthitis Syphilitica." Discussed by Drs. George M. Coates, Philadelphia; Norval H. Pierce, Chicago; Cullen F. Welty, San Francisco; Joseph D. Heitger, Louisville, Ky.; William B. Chamberlin, Cleveland; Harry L. Pollock, Chicago; H. B. Lemere, Omaha; E. Lee Myers, St. Louis, and George W. MacKenzie, Philadelphia.

Dr. Francis P. Emerson, Boston, read a paper on "Clinical Manifestations of the Infection of the Lateral Sinus." Discussed by Drs. Cullen F. Welty, San Francisco; John F. Barnhill, Indianapolis; Lee W. Dean, Iowa City; H. H. Martin, Savannah, Ga.; Leon E. White, Boston, and Francis P. Emerson, Boston.

Dr. Cullen F. Welty, San Francisco, read a paper on "New Method of Closing an Enlarged Tooth Root Opening into the Maxillary Antrum." Discussed by Drs. Joseph A. Stucky, Lexington, Ky.; Joseph C. Beck, Chicago, and Cullen F. Welty, San Francisco.

Dr. William V. Mullin, Colorado Springs, Colo., read a paper on "The Indifference of the Laryngologist Toward Tuberculous Laryngitis and the Tuberculosis Problem." Discussed by Drs. John B. McMurray, Washington, Pa.; T. E. Carmody, Denver; Joseph A. Stucky, Lexington, Ky.; Cullen F. Welty, San Francisco; Carl H. McCaskey, Indianapolis, and William V. Mullin, Colorado Springs, Colo.

Moved by Dr. Leon White, Boston, that this section convene Friday afternoon at 1:30 instead of 2 o'clock, and that exhibition of instruments take place before election of officers. Seconded and carried.

FRIDAY, APRIL 30—AFTERNOON

The meeting was called to order at 1:40 by the chairman.

Dr. Joseph L. Goodwin, Tazewell, Tenn., presented combined forceps and bronchoscope.

Dr. Augustus A. Hayden, Chicago, presented a method of tying knots around a mastoid bandage to keep it smooth and prevent the edges from stretching.

Dr. M. M. Cullom, Nashville, Tenn., presented an adenotome that can be also used as a curet, also a pair of bifocal glasses to be used when examining the nose.

The secretary read the report of the Committee on Caustic Alkalis. It was moved by Dr. Charles W. Richardson, Washington, D. C., that the report be accepted and the committee continued. Seconded and carried.

The secretary read the report of the Committee on Undergraduate and Graduate Teaching of Otolaryngology. It was moved by Dr. Charles W. Richardson, Washington, D. C., that the report be accepted and the committee continued. Seconded and carried.

The following officers were elected: chairman, Ross H. Skillern, Philadelphia; vice chairman, Richmond McKinney, Memphis, Tenn.; secretary, William B. Chamberlin, Cleveland; delegate, John F. Barnhill, Indianapolis.

Dr. Emil Mayer, New York, read the report of the Committee on Necrology. It was moved by Dr. William B. Chamberlin that this report be accepted, that the thanks of the section be extended to Dr. Emil Mayer, New York, for his work in preparing this report, and that the members of the section rise for a moment in honor of the departed members. Seconded and carried.

Dr. Charles W. Richardson, Washington, D. C., read the report of the Committee on the Education of the Deaf Child. It was moved by Dr. Wendell C. Phillips, New York, that the report be accepted. Seconded and carried.

Moved by Dr. Wendell C. Phillips, New York, that the scope of this work be extended to include the deaf child as well as the deaf adult, and that the investigations of this committee be carried out along all lines of deafness. Seconded by Dr. Emil Mayer, New York.

Dr. W. B. Chamberlin, Cleveland, offered an amendment to the effect that the committee be increased from three to five

members, and that the investigation include work along the line of education of the deaf adult. Motion seconded and the amended motion carried.

Dr. Emil Mayer, New York, read a special report on local anesthesia by the Committee on Therapeutic Research.

Moved by Dr. Francis P. Emerson, Boston, that the recommendations of the Committee on Local Anesthesia be adopted; that is, that this section endorse the plan for the investigation of new remedies by members of the American Medical Association, when the Council on Pharmacy has concluded its examinations; also that the chairman appoint a permanent committee of four on the toxic effects of local anesthetics, one member to be the secretary of the section, this committee to report at the next annual meeting. Seconded and carried.

The special report of the Committee on Local Anesthesia was discussed by Dr. Rudolph Matas, New Orleans, and Dr. Carroll W. Allen, New Orleans.

Moved by Dr. S. G. Higgins, Milwaukee, that the discussion of papers be limited to those men whose names appear on the program. Seconded and carried.

The discussion of the report of the Committee on Local Anesthesia was closed by Dr. Emil Mayer, New York.

The newly elected chairman, Dr. Ross H. Skillern, Philadelphia, took the chair.

Dr. Leon E. White, Boston, read a paper on "The Diagnosis and Prognosis of Loss of Vision from Accessory Sinus Disease." Discussed by Drs. S. G. Higgins, Milwaukee, and Leon E. White, Boston.

Dr. Owen Smith, Portland, Maine, read a paper on "Harelip and Cleft Palate." Discussed by Dr. T. E. Carmody, Denver.

Dr. Henry H. Briggs, Asheville, N. C., read a paper on "Relative Value of Transillumination and Roentgenography in the Diagnosis of Disease of the Maxillary and Frontal Sinuses; with Description of an Orbitopalatal Route of Transilluminating the Maxillary Sinus." Discussed by Drs. Joseph C. Beck, Chicago, and H. H. Briggs, Asheville, N. C.

Dr. Robert G. Reaves, Greensboro, S. C., read a paper on "Nerve Blocking for Nasal Surgery." Discussed by Drs. H. H. Martin, Savannah, Ga., and by Robert G. Reaves, Greensboro, S. C.

The chairman announced that the Committee on Local Anesthesia would consist of the old committee with the addition of the secretary of the section.

SECTION ON DISEASES OF CHILDREN

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Fritz B. Talbot, Boston.

Dr. Fritz B. Talbot, Boston, read the chairman's address, entitled "The Future of Pediatrics."

The secretary announced the dinner of the section to be held at the Hotel Grunewald, Thursday evening at 7 o'clock. He also announced that Dr. and Mrs. Laurence R. DeBuys, New Orleans, had invited the section to a tea at their home, Thursday afternoon from 4 to 6.

Dr. John Lovett Morse, Boston, read a paper on "The Treatment of Indigestion in Children." Discussed by Drs. L. W. Hill, Boston; C. G. Grulee, Chicago; L. T. Lewald, New York; I. A. Abt, Chicago, and John L. Morse, Boston.

Dr. Harry M. McClanahan, Omaha, read a paper on "The Treatment of Indigestion in Children from Six to Twelve Years of Age." Discussed by Drs. Laurence R. DeBuys, New Orleans; H. D. Chapin, New York; John Lovett Morse, Boston; Lydia Allen DeVilbiss, Washington, D. C.; G. D. Scott, New York; Fred Moore, Des Moines, Iowa, and Harry M. McClanahan, Omaha.

Dr. C. Hilton Rice, Jr., Montgomery, Ala., read a paper on "The Relation of the Acquired Food Dislikes of Childhood to the Ills of Middle Life." Discussed by Drs. William Walton Butterworth, New Orleans; Fritz B. Talbot, Boston; May G. Wilson, New York; O. M. Gilbert, Boulder, Colo., and C. Hilton Rice, Jr., Montgomery, Ala.

Dr. William A. Mulherin, Augusta, Ga., read a paper on "Three Pertinent Questions on Maternal Feeding." Discussed by Dr. John Lovett Morse, Boston; James D. Love, Jacksonville, Fla.; I. A. Van Zandt, Fort Worth, Texas; A. J. Scott, Jr., Los Angeles; L. H. Roddy, Waco, Texas; William Weston, Jr., Columbia, S. C.; Charles James Bloom, New Orleans, and William A. Mulherin, Augusta, Ga.

Dr. Henry Dwight Chapin, New York, read a paper on "How Pediatric Teaching of Nutrition May Affect the Nation's Welfare." Discussed by Drs. John A. Foote, Washington, D. C.; Lewis W. Hill, Boston, and Henry Dwight Chapin, New York.

Dr. George Dow Scott, New York, read a paper on "The Clinical Value of Vegetable Oils in Certain Abnormal Conditions of Infancy and Childhood." No discussion.

THURSDAY, APRIL 29—MORNING

The meeting was called to order at 9 o'clock by the chairman.

Dr. William Weston, Columbia, S. C., read a paper on "Acrodynia." Discussed by Drs. A. H. Byfield, Iowa City; Joseph Goldberger, Washington, D. C., and William Weston, Columbia, S. C.

Drs. Warren R. Sisson and W. Denis, Boston, presented a paper on "Observations on the Salt Content of Breast Milk." Discussed by Dr. Fritz B. Talbot, Boston.

Dr. Lewis Webb Hill, Boston, read a paper on "Chronic Nephritis in Children." Discussed by Drs. C. F. Wahrer, Fort Madison, Iowa; John Lovett Morse, Boston; G. D. Scott, New York; H. M. McClanahan, Omaha, and Lewis Webb Hill, Boston.

Dr. Edgar J. Huenekens, Minneapolis, presented a paper on "Infantile Spinal Progressive Muscular Atrophy (Werdnig-Hoffmann)." Discussed by Drs. Frank C. Neff, Kansas City, Mo.; John Zahorsky, St. Louis, and Edgar J. Huenekens, Minneapolis.

Dr. Richard S. Eustis, Boston, read a paper on "Newer Ideas of Heart Disease Applied to Pediatrics." Discussed by Drs. George D. Scott, New York; Julius H. Hess, Chicago; A. J. Scott, Jr., Los Angeles; John M. Dodson, Chicago; Isaac A. Abt, Chicago, and Richard S. Eustis, Boston.

Dr. May G. Wilson, New York, read a paper on "Circulatory Reactions in Normal Children after Exercise." Discussed by Drs. Alexander Lambert, New York; Mand Loeber, New Orleans; William St. Lawrence, New York; Laurence R. DeBuys, New Orleans; Fritz B. Talbot, Boston; E. C. Fleischner, San Francisco, and May G. Wilson, New York.

Dr. Henry J. Cartin, Johnstown, Pa., read a paper on "Intubation of the Larynx." Discussed by Drs. Isaac A. Abt, Chicago; L. T. Royster, Norfolk, Va.; A. J. Scott, Jr., Los Angeles; George D. Scott, New York; John Zahorsky, St. Louis; John A. Foote, Washington, D. C.; Howard B. Hamilton, Omaha; Solon G. Wilson, New Orleans, and H. J. Cartin, Johnstown, Pa.

FRIDAY, APRIL 30—MORNING

The meeting was called to order at 9 o'clock by the chairman.

The following officers were elected: chairman, Dr. Frank C. Neff, Kansas City, Mo.; vice chairman, Dr. William Weston, Jr., Columbia, S. C.; delegate, Dr. Isaac A. Abt, Chicago.

Dr. Julius P. Sedgwick, Minneapolis, read the subjoined report of the Child Welfare Committee:

Your committee, in submitting its report, desires first to call attention to the resolution adopted at the last annual meeting of the section, wherein its functions are defined:

Resolved, That it is the sense of this meeting that a committee be appointed to consider the question of child welfare more fully during the coming year; that it be instructed to meet with whatever agency it sees fit, submitting its problems to the Council on Health and Public Instruction of the American Medical Association, and to promote the interests of children by bringing the pediatricist of the country into more intimate touch with the movement, by whatever other means may seem expedient.

In June of 1919, after the adjournment of the American Medical Association, a conference was held by your committee with Dr. Anna E. Rude, of the Child Hygiene Division, Children's Bureau, at which

time her attention was called to the attitude of the profession of the country toward the Children's Bureau. A request was made that Miss Julia C. Lathrop of the Children's Bureau should confer with your committee, and representatives of the American Children's Hygiene Association and the American Pediatric Society, in Atlantic City.

This conference was subsequently held, and the two following concurrent criticisms explained to Miss Lathrop: first, that the medical profession was absolutely opposed to the method whereby the state committees for the Children's Year were appointed without any consideration being taken as to the attitude of the medical profession on those appointees; second, that the policy of the Children's Bureau of publishing medical literature under the authorship of lay women was absurd, and conducive to disorganization.

After a plain discussion, it was suggested that the difficulties could be overcome by the appointment to the Child Hygiene Division of the Children's Bureau, of an advisory committee, consisting of one member nominated by the American Medical Association, one member nominated by the American Child Hygiene Association, and one member nominated by the American Pediatric Society.

Inasmuch as the nomination of a member representing the American Medical Association was a function of the Council on Health and Public Instruction, the whole matter was discussed with that council, and the name of Julius H. Hess, suggested by your committee as the representative of the American Medical Association.

Dr. Hess was informed by the Council on Health and Public Instruction, and appointed by Miss Lathrop to this Advisory Committee.

Dr. Julius H. Hess, Chicago, submitted the following report:

Report of the members of the Child Welfare Committee of the Section on Diseases of Children of the American Medical Association, by its nominee to the Advisory Committee to the Division of Child Hygiene of the Children's Bureau:

All of the members of the Advisory Committee, consisting of Richard M. Smith, representing the American Pediatric Society, Dr. Howard C. Carpenter, representing the American Child Hygiene Association, and Dr. Julius H. Hess, representing the American Medical Association, met with Dr. Anna E. Rude, of the Division of Child Hygiene, of the Children's Bureau, in Boston, Oct. 7, 1919. The committee made extensive suggestions for revision of the text of the pamphlet by Dr. Mendenhall on "Infant Feeding." This revised material will probably be submitted to the committee for further suggestions within the next two months. The pamphlet on "Infant Care" by Mrs. Max West has been sent to the members of the committee for advice as to changes in the text, as a preliminary to a meeting of the committee to be held in Chicago, June 3, 1920.

The committee has also suggested the advisability of issuing the pamphlet in the name of the Children's Bureau, with credit for compilation in the preface rather than, as heretofore, on the cover of the pamphlet.

Your committee wishes to express its appreciation for the spirit of cooperation manifested by Dr. Anna E. Rude of the Children's Hygiene Division of the Children's Bureau, toward the Advisory Committee. Only by such cooperation can the best results be achieved.

In view of the tremendous importance of the subject, your section is urged to undertake, through your Child Hygiene Committee, an intensive educational campaign on breast feeding.

Since it seems to be the consensus of opinion of the members of this section that breast feeding should be stressed in every possible way; and inasmuch as there are carried in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION certain advertisements of proprietary infants' foods which are not consistent with this opinion, your committee feels that the matter of their publication should be taken up with the management of THE JOURNAL.

Inasmuch as the various problems in child hygiene require constant attention, your committee further recommends that the chairman-elect of this section appoint a standing committee of five to assume these responsibilities, which committee shall be known as the Child Hygiene Committee on the Section of Diseases of Children of the American Medical Association.

On motion duly made, seconded and unanimously carried, this report was adopted by the section.

Dr. E. C. Fleischner: Mr. Chairman, it has been the custom of the Council on Scientific Assembly of the American Medical Association to hold each year in Chicago a conference with the secretaries of all the sections, in order to have a better understanding of the work of the Scientific Assembly, among the members of the various sections.

The secretary presented the following standing rules to be adopted by the section:

First, no paper shall occupy more than fifteen minutes in its presentation before the section. (Sec. 2, Chap. 11, By-Laws).

"The time allowed for the presentation of a paper before a section shall be limited to fifteen minutes" shall be mandatory, with the exception that the time may be extended by the unanimous consent of those present when the speaker is an invited guest of the section. The section shall not exercise this privilege, to extend the time for the discussion of a paper beyond the time allotted, five minutes, but this time limit shall be mandatory.

Second, with the exception that the reader of the paper may be permitted to close the discussion, a Fellow shall be permitted to take part in the discussion of a paper once and only once.

Third, any Fellow who desires to discuss a paper shall be required to give in writing his name, together with his home and local annual session address to the secretary of the section before he is given the floor. This rule shall be strictly enforced when for the first time in

the annual session a Fellow takes part in the discussions of the section.

Fourth, each author shall hand his paper to the secretary of the section after reading. This requirement shall be amplified and emphasized, and shall be construed to require that each author must present to the secretary of the section a finished copy of his paper before he is permitted to present his contribution to the section.

Fifth, each author shall be required to send one synopsis of his paper to each of those listed in the official program to open the discussion of the paper, and these synopses shall be mailed to those assigned to open the discussions, at least ten days before the first day assigned for the meetings of the section.

Sixth, the secretary of the section shall inform himself as to whether or not each member of the Executive Committee of his section expects to be in attendance at each annual session of the Association, and shall transmit to the chairman of the section the information he receives, reporting both who of the Executive Committee of the section plan to be in attendance, and also who will probably not be present.

Seventh, the secretary of the section shall mail a copy of the rules of the section to each Fellow who is assigned to a place on the program of the section.

Eighth, the rules of the section shall be binding on the secretary of the section, who shall have no option, but must enforce them.

Nine, when two or more sections unite for the purpose of a symposium, the officers of the sections united shall select from among their numbers, a chairman, a secretary and an executive committee of three, and the same shall function as the officers of the joint meeting.

On motion duly seconded and carried, the rules were adopted.

It was moved by Dr. Harry M. McClanahan, Omaha, and was duly seconded and carried, that a committee be appointed to wait on Dr. Franklin P. Gegenbach, Denver, and to report back to the section. The chairman appointed as such committee Drs. Harry M. McClanahan, Omaha, and M. L. Turner, Des Moines, Iowa.

Dr. Isaac A. Abt, Chicago, moved that a committee of two be appointed to draw up an appropriate memorial to Dr. Abraham Jacobi, New York, and to present it at the next annual meeting. Seconded and carried. The chairman appointed as such committee Drs. Isaac A. Abt, Chicago, and H. F. Helmholz, Chicago.

Drs. William E. Carter, San Francisco, and Langley Porter, San Francisco, presented a paper on "Observations on Tumors of the Kidney in Children." Discussed by Dr. L. T. LeWald, New York, Sir Humphry Davy Rolleston, London, England, and Dr. W. E. Carter, San Francisco.

Dr. J. Ross Snyder, Birmingham, Ala., read a paper on "The Temporary Teeth Disorders Due to Their Neglect." Discussed by Drs. Julius P. Sedgwick, Minneapolis; Isaac A. Abt, Chicago; W. L. Funkhouser, Atlanta, Ga.; C. F. Wahrer, Fort Madison, Iowa; Laurence R. DeBuys, New Orleans; Fritz B. Talbot, Boston; E. C. Fleischner, San Francisco, and J. Ross Snyder, Birmingham, Ala.

Dr. Turner reported for the committee appointed to call on Dr. F. P. Gegenbach that the Doctor was improving.

Dr. Frederick C. Rodda, Minneapolis, read a paper on "The Coagulation Time of Blood in the New-Born with Special Reference to Cerebral Hemorrhage." Discussed by Drs. Isaac A. Abt, Chicago; John Foote, Washington, D. C.; Howard B. Hamilton, Omaha, and Frederick C. Rodda, Minneapolis.

Dr. Josiah J. Moore, Chicago, read a paper on "The Antiscorbutic Value of Proprietary Baby Foods." Discussed by Dr. Julius H. Hess, Chicago.

Dr. Hugh McCulloch, St. Louis, read a paper on "Studies of the Effect of Diphtheria Toxin on the Heart." Discussed by Drs. Richard S. Eustis, Boston, and Fritz B. Talbot, Boston.

Dr. Thomas D. Parke, Birmingham, Ala., read a paper on "Intramuscular Blood Injections as Nutritional Aids." Discussed by Dr. Fritz B. Talbot, Boston.

Dr. Robert E. Farr, Minneapolis, read a paper on "Local Anesthesia in Infancy and Childhood." Discussed by Drs. Martin B. Tinker, Ithaca, N. Y.; Edgar J. Huenekens, Minneapolis, and Robert E. Farr, Minneapolis.

Dr. William Weston, Columbia, S. C., moved that the thanks of the section be returned to the officers of this section, and to Dr. Laurence R. DeBuys and the other members of the profession in New Orleans, who had contributed so generously toward the success of this meeting. Seconded and carried.

**SECTION ON PHARMACOLOGY AND
THERAPEUTICS**

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order at 9:15 by the chairman, Dr. George W. McCoy, Washington, D. C.

Dr. George W. McCoy read the chairman's address.

Dr. Cary Eggleston, New York, read a paper on "Clinical Observations on the Absorption of Digitalis." Discussed by Drs. Henry A. Christian, Boston; Leonard G. Rowntree, Minneapolis, and Cary Eggleston, New York.

Drs. Frederick M. Allen, J. W. Mitchell and J. W. Sherrill, New York, presented a paper on "The Treatment of Combined Diabetes and Nephritis." Discussed by Drs. George Norris, Philadelphia; Leonard G. Rowntree, Minneapolis, and F. M. Allen, New York.

Dr. Henry A. Christian, Boston, read a paper on "Deficiencies in Our Methods of Treatment of Chronic Nephritis." Discussed by Drs. Lewellys F. Barker, Baltimore; George Dock, St. Louis; Nelson W. Janney, Santa Barbara, Calif.; Eugene S. Kilgore, San Francisco, and Henry A. Christian, Boston.

The chairman appointed a nominating committee consisting of Drs. J. T. Halsey, New Orleans, chairman; F. M. Allen, New York, and George B. Roth, Washington, D. C.

In the absence of the other members of the executive committee, the chairman appointed Drs. Leonard G. Rowntree, Minneapolis, and Carl Voegtlin, Washington, D. C., to serve with himself on that committee.

The standard rules of the section were read. It was moved and seconded that the rules be adopted as printed and made effective at once. Carried.

THURSDAY, APRIL 29—AFTERNOON

A joint meeting was held with the Section on Dermatology. For a report of the proceedings, see the minutes of that section.

FRIDAY, APRIL 30—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. George W. McCoy, Washington, D. C.

The following officers were elected: chairman, Leonard G. Rowntree, Minneapolis; vice chairman, Carl Voegtlin, Washington, D. C.; secretary, Cary Eggleston, New York (continued); alternate delegate, Robert A. Hatcher, New York; executive committee, W. A. Bastedo, New York; George W. McCoy, Washington, D. C., and L. G. Rowntree, Minneapolis.

Lewis E. Warren, Chicago, and Robert P. Fishelis, Philadelphia, were elected to Associate Fellowship.

Drs. Leonard G. Rowntree, Albert M. Snell and Frances Ford, Minneapolis, presented a paper on "Factors Affecting the Basal Metabolic Rate." Discussed by Drs. Nelson W. Janney, Santa Barbara, Calif.; H. S. Plummer, Rochester, Minn.; B. C. Lockwood, Detroit, and L. G. Rowntree, Minneapolis.

Drs. Gerardo M. Balloni and Paul D. White, Boston, presented a paper on "Clinical Observations on the Digitalis-Like Action of Squills." Discussed by Drs. J. T. Halsey, New Orleans; Cary Eggleston, New York, and G. M. Balloni, Boston.

Drs. Carl Voegtlin and Homer W. Smith, Washington, D. C., presented a paper on "Quantitative Studies in Chemotherapy." Discussed by Drs. George B. Roth, Gleason C. Lake and Carl Voegtlin, Washington, D. C.

SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY, APRIL 28—AFTERNOON

The meeting was called to order at 2:15 by the secretary, Dr. J. J. Moore, Chicago. In the absence of the regular chairman, Dr. Howard T. Karsner, Cleveland, Dr. E. R. Le Count, Chicago, was appointed temporary chairman.

Dr. Benjamin Taylor Terry, Nashville, Tenn., read a paper on "Increasing the Pathologist's Usefulness and Rewards." Discussed by Drs. William C. MacCarty, Rochester, Minn., and B. T. Terry, Nashville, Tenn.

Drs. Joseph Goldberger and George A. Wheeler, Washington, D. C., presented a paper on "Experimental Pellagra in White Male Convicts."

Dr. James W. Babcock, Columbia, S. C., read a paper on "Review of the Recent Reports on Pellagra." These two papers were discussed by Drs. Martin F. Engman, St. Louis; Marcus Haase, Memphis, Tenn.; D. W. Kelly, Winnfield, La.; A. A. Herold, Shreveport, La.; Joseph Goldberger, Washington, D. C., and James Babcock, Columbia, S. C.

Dr. Ludvig Hektoen, Chicago, read a paper on "The Toxic Substances Produced by Hemolytic Streptococci." Discussed by Drs. E. R. Le Count, Chicago; Clyde Brooks, Columbus, Ohio, and Ludvig Hektoen, Chicago.

Drs. Clyde Brooks and Albert M. Bleile, Columbus, Ohio, presented a paper on "Recent Advances in Clinical Blood Pressure Measurement." Discussed by Dr. E. S. Kilgore, San Francisco, and Clyde Brooks, Columbus, Ohio.

Dr. William S. Carter, Galveston, Texas, read a paper on "An Experimental Study of Acidosis Produced by Ether Anesthesia." No discussion.

It was moved, seconded and carried that the following applicants be accepted for associate membership: Thésle T. Job, Oak Park, Ill.; Frank P. McNamara, New Haven, Conn., and James W. Jobling, Nashville, Tenn.

It was moved, seconded and carried that the following foreign guests be admitted to honorary membership: Norman Walker, Edinburgh, Scotland; Col. H. J. Waring, London; Sir Humphry D. Rolleston, London; Dr. E. E. Desmarest, Paris; Dr. Gustave Roussy, Paris; Dr. Jules Voncken, Liège, Belgium, and Dr. Iwaho Tsuchiya, Tokyo, Japan.

It was moved, seconded and carried that the standard rules for the section be adopted as printed.

In the absence of the official executive committee, Drs. D. J. Davis, E. R. Le Count and Ludvig Hektoen, all of Chicago, were asked to serve as a committee.

THURSDAY, APRIL 29—AFTERNOON

The meeting was called to order at 2:10 by the secretary, Dr. J. J. Moore, Chicago. Dr. D. J. Davis, Chicago, was asked to serve as temporary chairman.

Dr. James H. Black, Dallas, Texas, read a paper on "The Development of the Bactericidal Power of Whole Blood and of Antibodies in the Serum." Discussed by Dr. D. J. Davis, Chicago.

Dr. D. J. Davis, Chicago, read a paper on "Some Characteristics of Certain Epidemic Micro-Organisms." No discussion.

Dr. Kenneth M. Lynch, Charleston, S. C., read a paper on "Penetration of the Intestine and Formation of Abdominal Abscess by Endameba Histolytica." No discussion.

Dr. Carleton Dederer, Bay City, Mich., read a paper on "Transplantation of the Kidney and Ovary." Discussed by Drs. V. D. Lespinasse, Chicago; William C. MacCarty, Rochester, Minn.; Clyde Brooks, Columbus, Ohio, and Carleton Dederer, Bay City, Mich.

Dr. William C. MacCarty, Rochester, Minn., read a paper on "A Mathematical Terminology for Neoplasia." Discussed by Drs. D. J. Davis, Chicago; Carleton Dederer, Bay City, Mich., and William C. MacCarty, Rochester, Minn.

Dr. Louis A. Turley, Norman, Okla., read a paper on "Chronic Nephritis with Special Reference to the Interstitial Form." Discussed by Dr. Robert H. Blackman, Shreveport, La.

FRIDAY, APRIL 30—AFTERNOON

The meeting was called to order at 2:10 by the secretary, Dr. J. J. Moore, Chicago. Dr. F. F. Russell, Washington, D. C., was appointed temporary chairman.

The nominating committee, consisting of Drs. A. M. Moody, Chicago, and F. S. Graves, Louisville, Ky., reported the following nominations: Chairman, Dr. E. R. Le Count, Chicago; vice chairman, Dr. William S. Carter, Galveston, Texas; secretary, Dr. J. J. Moore, Chicago, and delegate, Dr. James Ewing, New York. On motion duly made and seconded they were declared elected.

Dr. Ward T. Burdick, Denver, read a paper on "The Wassermann Reaction: Prolonged Incubation in the Icebox Versus a Short Period Over the Water Bath." Discussed by Drs. John A. Kolmer, Philadelphia; C. C. Bass, New Orleans, and Ward Burdick, Denver.

Dr. A. M. Moody, Chicago, read a paper on "Bacterial Vaccines, Their Uses and Abuses." Discussed by Drs. G. W. McCoy, Washington, D. C.; James H. Black, Dallas, Texas; H. J. Nichols, Washington, D. C.; J. J. Moore, Chicago; Herman Spitz, Nashville, Tenn., and A. M. Moody, Chicago.

Dr. F. Stuart Graves, Louisville, Ky., read a paper on "The Value of the Postmortem Wassermann Reaction." Discussed by Drs. A. M. Moody, Chicago; Ward Burdick, Denver; R. G. Owen, Detroit; F. F. Russell, Washington, D. C.; John A. Kolmer, Philadelphia; F. M. Johns, New Orleans, and F. S. Graves, Louisville, Ky.

Dr. John J. Seelman, Milwaukee, read a paper on "Observations on the Quantitative Nature of Complement Fixation." Discussed by Drs. Frank J. Hall, Kansas City, Mo.; Ward Burdick, Denver; F. S. Graves, Louisville, Ky.; W. C. Jones, Birmingham, Ala., and J. J. Seelman, Milwaukee.

Drs. W. Warner Watkins and Clarence N. Boynton, Phoenix, Ariz., presented a paper on "The Complement Fixation Reaction in Tuberculosis." Discussed by Drs. Ward Burdick, Denver; W. H. Harris, New Orleans; F. M. Johns, New Orleans; W. O. Jones, Birmingham, Ala.; Frank J. Hall, Kansas City, Mo., and W. Warner Watkins, Phoenix, Ariz.

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order by the vice chairman, Dr. Arthur S. Hamilton, Minneapolis.

On motion by Dr. C. R. Woodson, St. Joseph, Mo., carried, Drs. Hugh T. Patrick, Chicago; Karl A. Menninger, Topeka, Kan., and Edward L. Hunt, New York, were appointed as a committee to draft suitable resolutions on the death of Dr. Elmer E. Southard, and report at a subsequent session.

Drs. Ross Moore, Los Angeles; William A. Jones, Minneapolis, and Roy M. Van Wart, New Orleans, were appointed to act on the executive committee.

Dr. Arthur S. Hamilton, Minneapolis, read the chairman's address, entitled "Some Changes in the Nervous System in Pernicious Anemia, Especially Sensory Changes."

Dr. Edmund Jacobson, Chicago, read a paper on "Reduction of Nervous Irritability and Excitement by Progressive Relaxation." Discussed by Drs. Tom A. Williams, Washington, D. C.; Hyman Climenko, New York, and Edmund Jacobson, Chicago.

Dr. Gustave Roussy, professor of medicine, University of Paris, France, was introduced by Dr. Hugh T. Patrick, Chicago. In response to the cordial welcome extended, Professor Roussy expressed his pleasure in being present on this occasion and in meeting with the great American Medical Association, whose name is so well known in France. He expressed pleasure concerning the close association of American and French neurologists which has been brought about through the war, and voiced the desire that the relations of French and American institutions might continue—that the French might come to American colleges and learn of us, and we go to their educational institutions and learn of them, and so cultivate that broad spirit which makes for the best relations between nations.

Dr. Karl A. Menninger, Topeka, Kan., read a paper on "Influenza and Feeble-mindedness." Discussed by Drs. Andrew L. Skoog, Kansas City, Mo.; Hyman Climenko, New York; Oscar J. Raeder, Boston; Tom A. Williams, Washington, D. C.; C. F. Neu, Indianapolis, and Karl A. Menninger, Topeka, Kan.

Dr. Sanger Brown, Chicago, read a paper on "Outline of a Scheme for Writing the Natural History of Syphilis." Discussed by Drs. C. R. Woodson, St. Joseph, Mo., and Sanger Brown, Chicago. In concluding his paper, Dr. Brown intro-

duced and moved the adoption of the subjoined preambles and resolutions:

WHEREAS, The deleterious effects of syphilis on the mortality and morbidity of the human race are so prevalent and so severe as to challenge the most serious attention of the medical profession; and

WHEREAS, In the scientific study of any disease, knowledge of its natural history is a matter of cardinal importance; and

WHEREAS, Owing to the protracted course of syphilis, a continuous, complete clinical record of a given case can be secured only through the services of several successive medical observers; and

WHEREAS, It is highly desirable that a sufficient number of completed histories be accumulated and preserved and made easily accessible to students; and

WHEREAS, For the successful accomplishment of the purpose set forth above, the interest and cooperation of the best elements of our profession as represented in the membership of the American Medical Association are necessary; therefore, be it

Resolved, That the Section on Nervous and Mental Diseases of the American Medical Association recognizes the importance of ascertaining the natural history of syphilis and of making the history accessible for the information of students of medicine; and be it further

Resolved, That the Section on Nervous and Mental Diseases of the American Medical Association respectfully requests the trustees of the American Medical Association to appoint a committee from the sections most immediately concerned whose duty it should be to devise practical means and methods of accomplishing the foregoing specified purpose; and be it further

Resolved, That the representatives of the section in the House of Delegates be requested to present these preambles and resolutions to the House of Delegates and to ask its endorsement.

See minutes of the House of Delegates.

Dr. Hugh T. Patrick, Chicago, moved the adoption of the resolutions. Motion seconded by Dr. W. S. Lindsay, Topeka, Kan., and unanimously carried.

The following members were appointed to act as the nominating committee: Drs. George A. Moleen, Denver; Frank R. Fry, St. Louis, and Walter Timme, New York.

Dr. William A. Jones, Minneapolis, read a paper on "Discussion of Therapeutic Agents in Chronic Nervous Diseases." Discussed by Drs. Frank R. Fry, St. Louis; Ross Moore, Los Angeles; C. R. Woodson, St. Joseph, Mo.; Hyman Climenko, New York; W. T. Williamson, Portland, Ore., and William A. Jones, Minneapolis.

Dr. Frank R. Fry, St. Louis, read a paper on "Congenital Facial Paralysis: Two Additional Cases." No discussion.

THURSDAY, APRIL 29—MORNING

The section was called to order by the chairman at 9:30.

Dr. Julius Grinker, Chicago, read a paper on "Experiences with Luminal in Epilepsy." Discussed by Drs. George A. Moleen, Denver; Marvin L. Graves, Galveston, Texas; Andrew L. Skoog, Kansas City, Mo.; David S. Booth, St. Louis; E. Bates Block, Atlanta, Ga.; F. B. Wynn, Indianapolis; Roy M. Van Wart, New Orleans, and Julius Grinker, Chicago.

Dr. Hugh T. Patrick, Chicago, presented the report of the committee appointed to draft resolutions on the death of Dr. Elmer E. Southard, as follows:

WHEREAS, Dr. Elmer E. Southard, who one year ago was elected chairman of the Section on Nervous and Mental Diseases of the American Medical Association and should have presided at this session, has been removed by death; and

WHEREAS, Dr. Southard was a trained pathologist, a gifted neurologist, an able psychiatrist, an author of distinction, a brilliant teacher, a genial companion and a loyal friend; therefore be it

Resolved, That in the death of Dr. Southard the medical profession and especially the departments of neurology and psychiatry have suffered an irreparable loss; and be it further

Resolved, That the members of this section extend to the family of Dr. Southard their profound sympathy.

On motion duly seconded and carried, the foregoing preambles and resolutions were adopted by the section.

Dr. Oscar J. Raeder, Boston, read a paper on "Endocrine Imbalance in the Feeble-minded." Discussed by Drs. Tom A. Williams, Washington, D. C.; Gustave Roussy, Paris, France; Walter Timme, New York; M. A. Bliss, St. Louis; Andrew L. Skoog, Kansas City; Karl A. Menninger, Topeka, Kan., and Oscar J. Raeder, Boston.

Dr. I. Leon Meyers, Chicago, read a paper on "The Physiologic Significance of the Babinski Toe Response." Discussed by Drs. Andrew L. Skoog, Kansas City; Tom A. Williams,

Washington, D. C.; Gustave Roussy, Paris, France; M. A. Bliss, St. Louis, and I. Leon Meyers, Chicago.

FRIDAY, APRIL 30—MORNING

The meeting was called to order at 9:30 by the chairman.

The following officers were elected for the ensuing year: chairman, Dr. Arthur S. Hamilton, Minneapolis; vice chairman, Dr. Walter Timme, New York; secretary, Dr. Charles W. Hitchcock, Detroit (continued), delegate, Dr. Hugh T. Patrick, Chicago.

Drs. Isador Abrahamson and Hyman Climenko, New York, presented a paper on "Symptomatology of Spinal Cord Tumors with Illustrative Cases." Discussed by Drs. Julius Grinker, Chicago; Alfred W. Adson, Rochester, Minn.; A. L. Skoog, Kansas City, Mo.; Karl A. Menninger, Topeka, Kan.; M. A. Bliss, St. Louis; George A. Moleen, Denver; Tom A. Williams, Washington, D. C., and Hyman Climenko, New York.

Dr. Tom A. Williams, Washington, D. C., read a paper on "The Causes of Emotivity and Their Management." Discussed by Drs. Julius Grinker, Chicago; David S. Booth, St. Louis; Hyman Climenko, New York; Karl A. Menninger, Topeka, Kan.; C. F. Neu, Indianapolis; Ross Moore, Los Angeles; G. H. Benton, Miami, Fla.; Gustave Roussy, Paris, France; George A. Moleen, Denver, and Tom A. Williams, Washington, D. C.

Dr. A. L. Skoog, Kansas City, Mo., read a paper on "Measles: Brain Complications." Discussed by Drs. Karl A. Menninger, Topeka, Kan., and A. L. Skoog, Kansas City.

Dr. E. Bates Block, Atlanta, Ga., read a paper on "The Relation of Worms to Epilepsy." Discussed by Drs. Julius Grinker, Chicago; David S. Booth, St. Louis; Hyman Climenko, New York; Martin L. Graves, Galveston, Texas; Tom A. Williams, Washington, D. C., and E. Bates Block, Atlanta.

Dr. Edward Livingston Hunt, New York, read a paper on "Encephalitis Lethargica." Discussed by Drs. Frank R. Fry, St. Louis; Julius Grinker, Chicago; Tom A. Williams, Washington, D. C.; Ross Moore, Los Angeles; Hyman Climenko, New York; George A. Moleen, Denver; Oscar J. Raeder, Boston; A. L. Skoog, Kansas City, Mo.; Roy M. Van Wart, New Orleans; Albert Woldert, Tyler, Tenn., and David S. Booth, St. Louis.

SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order at 9:35 by the chairman, Dr. James A. Hayne, Columbia, S. C.

Dr. James A. Hayne, Columbia, S. C., read the chairman's address, entitled "The Rights of the Child."

Dr. Erwin A. Peterson, Washington, D. C., read a paper on "What the American Red Cross Can Contribute to the General Health Program." Discussed by Drs. J. W. Schereschewsky, Washington, D. C.; Philip King Brown, San Francisco; John D. McLean, Harrisburg, Pa.; John P. Davin, New York; C. W. Goddard, Austin, Texas; E. Luther Stevens, St. Augustine, Fla., and Erwin A. Peterson, Washington, D. C.

Dr. Frederick L. Hoffman, Newark, N. J., read a paper on "Mortality and Incidence of Leprosy Throughout the World." Discussed by Drs. Isadore Dyer, New Orleans; J. W. Schereschewsky, Washington, D. C.; G. C. Chandler, Shreveport, La.; John P. Davin, New York; Hiram Byrd, University, Miss.; S. W. Welch, Montgomery, Ala.; A. T. McCormack, Louisville, Ky.; V. G. Heiser, New York, and Frederick L. Hoffman, Newark, N. J.

Dr. A. T. McCormack, Louisville, Ky., read the following resolution and moved that it be accepted and presented to the House of Delegates:

WHEREAS, Leprosy is a national menace; therefore, be it

Resolved, That the House of Delegates be requested to ask that the American Public Health Association shall call a national conference to discuss every phase of the problem to the end that the public may be educated to the insidious spread of the disease, the possibility of cure or arrestation in the earliest stage of the disease, and the necessity of segregation.

Motion carried. (See minutes of the House of Delegates.)

Dr. Carroll Fox, Washington, D. C., read a paper on "Minimum Standards of Organization for Municipal Health Departments." Discussed by Drs. G. C. Chandler, Shreveport, La.; Walter H. Brown, Washington, D. C.; A. T. McCormack, Louisville, Ky., and Carroll Fox, Washington, D. C.

Dr. J. A. Watkins, Cincinnati, read a paper on "The Training of Industrial Physicians." Discussed by Drs. J. W. Schereschewsky, Washington, D. C., and Edward Martin, Philadelphia.

The chairman appointed Drs. A. T. McCormack, Louisville, Ky., and John W. Kerr, New York, on the Executive Committee to take the places of Drs. Otto P. Geier, Cincinnati, and W. S. Rankin, Raleigh, N. C.

THURSDAY, APRIL 29—MORNING

Dr. Charles M. Abbott, Alexandria, La., read a paper on "The Carrier Question in Epidemic Meningitis and Diphtheria." Discussed by Drs. L. I. Lobenhoffer, Alexandria, La.; H. J. Nichols, Washington, D. C.; G. W. McCoy, Washington, D. C.; C. A. Earle, Des Plaines, Ill.; A. Parker Hitchins, Indianapolis, and Charles M. Abbott, Alexandria, La.

Dr. Luther A. Riser, Columbia, S. C., read a paper on "Typhoid Reduction in South Carolina: Results in Counties with Health Organization." Discussed by Drs. W. S. Leathers, University, Miss.; J. D. McLean, Harrisburg, Pa.; G. C. Chandler, Shreveport, La.; John A. Ferrell, New York, and Luther A. Riser, Columbia, S. C.

Dr. J. W. Schereschewsky, Washington, D. C., read the following resolution and moved that it be accepted and presented to the House of Delegates:

WHEREAS, The National Tuberculosis Association, through investigations of its Committee on Indigent Migratory Consumptives, covering the last fifteen months, has found:

That there is a large migration of indigent consumptives to the Southwest in search of health;

That out of 1,786 patients, largely indigent or potentially indigent, reported from the Southwest in the last six months, 783, or 43.3 per cent., had been definitely advised to go there by physicians;

That this migration of indigent and potentially indigent consumptives is ill advised in that it causes much needless suffering and loss of life brought on by inadequate care, worry, homesickness and lack of proper food, which are conditions too frequently experienced after arrival; and furthermore,

That the migration of this group is a menace to the public health, both during migration and after arrival, and is a financial drain and social burden to the communities to which the migration goes. Therefore be it

Resolved, That in order to check this unnecessary and undesirable migration, physicians throughout the country be not only requested but urged not to advise their tuberculosis patients to migrate to the health resort states, unless such patients have sufficient funds to properly provide for their necessary care and comforts for at least one year.

Dr. Alexander Lambert, New York, presented the following amendment to the foregoing resolution, which amendment was accepted by Dr. J. W. Schereschewsky, Washington, D. C.:

Resolved, That the Section on Preventive Medicine and Public Health hereby requests the House of Delegates to instruct the Council on Health and Public Instruction to investigate and report at the next annual meeting the migration of consumptives from one state to the other throughout the Union, and the number of indigents, so foisted on one state by another, and report definite suggestions to prevent this constant undesirable migration.

The resolution, as amended, was duly seconded and carried. (See minutes of the House of Delegates.)

Dr. Lewis A. Conner, New York, read a paper on "Heart Disease as a Public Health Problem." Discussed by Drs. Alexander Lambert, New York; G. C. McKinney, Lake Charles, La.; William H. Mercier, Pittsburgh; John P. Davin, New York; B. A. Ledbetter, New Orleans, and Lewis A. Conner, New York.

Dr. Lunsford D. Fricks, Memphis, Tenn., read a paper on "Eradication of Malaria: A National Health Problem." Discussed by Drs. Graham E. Hensen, Jacksonville, Fla.; A. E. Chace, Texarkana, Ark.; C. C. Bass, New Orleans; W. S. Leathers, University, Miss.; J. W. Schereschewsky, Washington, D. C.; John A. Ferrell, New York; John P. Davin, New York, and Lunsford D. Fricks, Memphis, Tenn.

Dr. John McMullen, Louisville, Ky., read a paper on "Trachoma: A Public Health Problem of the States." Discussed by Dr. Arthur T. McCormack, Louisville, Ky.

Dr. J. Wilkerson Jervey, Greenville, S. C., read a paper on "The Differential Diagnosis of Conjunctival Folliculosis and Trachoma." These two papers were discussed by Drs. Henry Dickson Bruns, New Orleans; Theodore E. Oertel, Augusta, Ga.; James A. Hayne, Columbia, S. C.; Walter H. Brown, Washington, D. C.; S. W. Welch, Montgomery, Ala.; G. Golseth, Jamestown, N. D.; J. G. South, Frankfort, Ky.; John F. Hogan, Baltimore; Hiram Woods, Baltimore; John McMullen, Louisville, Ky., and J. Wilkerson Jervey, Greenville, S. C.

The chairman appointed the following nominating committee: Drs. C. St. Clair Drake, Springfield, Ill.; C. C. Bass, New Orleans, and A. T. McCormack, Louisville, Ky.

FRIDAY, APRIL 30—MORNING

The following officers were elected for the ensuing year: chairman, John D. McLean, Harrisburg, Pa.; vice chairman, C. D. Selby, Toledo, Ohio; secretary (three years), W. S. Leathers, University, Miss., and delegate, James A. Hayne, Columbia, S. C.

Dr. W. A. Sawyer, Rochester, N. Y., read a paper on "Industrial Epidemiology." Discussed by Drs. A. E. Chace, Texarkana, Ark.; John P. Davin, New York; James R. Bean, Birmingham, Ala.; S. W. Welch, Montgomery, Ala., and W. A. Sawyer, Rochester, N. Y.

Dr. A. E. Chace, Texarkana, Ark., read the following resolution and moved that it be accepted and presented to the House of Delegates:

Resolved, That the Section on Preventive Medicine and Public Health condemns the contract entered into by the United States Railroad Administration with railroad employees, whereby physical examination of applicants for employment is prohibited, and that it recommends to the House of Delegates the adoption of some resolution condemning in terms that cannot be mistaken the entering into of a contract with any labor organization prohibiting physical examination.

(Not transmitted to the House of Delegates.)

Dr. E. Luther Stevens, St. Augustine, Fla., presented the following amendment to the foregoing resolution, and moved its adoption:

Resolved, That a committee be appointed to investigate the question raised in the above resolution and report the result of its investigations at the first session of the Section on Preventive Medicine and Public Health at the next annual meeting of the American Medical Association.

The amendment was accepted by Dr. A. E. Chace, Texarkana, Ark., and carried.

Dr. Norman Walker of Edinburgh, Scotland, and Sir Humphry D. Rolleston of the Royal College of Physicians of London, England, who were in attendance at the annual meeting of the American Medical Association, were extended the privileges of the floor of this section.

Dr. Lloyd Noland, Birmingham, Ala., read a paper on "The Work of the Department of Health of the Tennessee Coal, Iron and Railroad Company." Discussed by Drs. S. W. Welch, Montgomery, Ala.; Walter C. Jones, Birmingham, Ala., and Oscar Dowling, New Orleans.

Dr. Grover C. McKinney, Lake Charles, La., read a paper on "The Difficulties of Public Health Administration." Discussed by Drs. G. C. Chandler, Shreveport, La.; James A. Hayne, Columbia, S. C.; H. F. White, Washington, D. C.; T. J. Howells, Salt Lake City; Milton Board, Louisville, Ky.; Mayer A. Newhauser, New Orleans; W. S. Leathers, University, Miss.; W. D. Calvin, Fort Wayne, Ind.; S. W. Welch, Montgomery, Ala.; John P. Davin, New York; Oscar Dowling, New Orleans, La., and Grover C. McKinney, Lake Charles, La.

Dr. Florence L. Meredith, New York, read the following resolution and moved it be accepted and presented to the House of Delegates:

WHEREAS, The number of graduates from medical schools in 1919 is reported to be nearly 900 short of the minimum estimated by the Carnegie Foundation as being necessary to carry on adequately the medical work of the country; and

WHEREAS, The growth of public health work calls for an increased number of doctors; and

WHEREAS, Women doctors have proved successful in preventive medicine and public health work; be it

Resolved, That the Section on Preventive Medicine and Public Health endorse efforts to enroll women as students in medical schools, and especially recommend to their attention the field of preventive medicine and public health.

After discussion by Drs. Milton Board, Louisville, Ky.; C. C. Bass, New Orleans; W. S. Leathers, University, Miss., and Florence L. Meredith, New York, the motion was carried. (Not transmitted to the House of Delegates.)

Dr. William Elder, New Orleans, read a paper on "The Necessity for the Reporting of Venereal Disease by Physicians." Discussed by Drs. Oscar Dowling, New Orleans; A. E. Chace, Texarkana, Ark.; W. D. Calvin, Fort Wayne, Ind.; Milton Board, Louisville, Ky.; Hardie R. Hays, North Carrollton, Miss.; H. F. White, Washington, D. C., and William Elder, New Orleans.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

WEDNESDAY, APRIL 28—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Oliver S. Ormsby, Chicago.

Dr. Oliver S. Ormsby, Chicago, read the chairman's address, entitled "A Valuable Method of Employing Arsenphenamin in Syphilis."

Dr. William A. Pusey, Chicago, presented the following preambles and resolutions on behalf of Dr. Sanger Brown, Kenilworth, Ill., who has in contemplation an effort to establish a bureau for the standardization of the histories of syphilis so that the end-results may be collated:

WHEREAS, The deleterious effects of syphilis on the mortality and morbidity of the human race are so prevalent and so severe as to challenge the most serious attention of the entire medical profession; and,

WHEREAS, In the scientific study of any disease, knowledge of its natural history is an item of cardinal importance; and

WHEREAS, Owing to the protracted course of syphilis, continuous and complete clinical record of a given case can be secured only through the services of several successive medical observers; and

WHEREAS, It is highly desirable that a sufficient number of completed histories be accumulated and preserved, and made easily accessible to students; and,

WHEREAS, For the successful accomplishment of the purpose set forth above, the interest and cooperation of a considerable number of the best elements of our profession as represented in the membership of the American Medical Association are necessary, therefore be it

Resolved, (1) That the Section on Dermatology and Syphilology recognizes the importance of ascertaining the natural history of syphilis and of making this history accessible and in form serviceable to students of medicine; further

Resolved, (2) That the Section on Dermatology and Syphilology respectfully requests the trustees of the American Medical Association to appoint a committee from the sections most immediately concerned, whose duty it shall be to devise practical means and methods of accomplishing the foregoing specified purpose; and further,

Resolved, (3) That the representatives of this section in the House of Delegates be requested to present these preambles and resolutions to the House of Delegates, and to ask its endorsement.

Dr. Pusey moved that these resolutions be adopted and transmitted to the House of Delegates as the expression of the opinion of those in attendance at this meeting. Seconded by Dr. Richard L. Sutton, Kansas City, Mo., and several others. Carried.

(See minutes of the House of Delegates.)

The chairman appointed a nominating committee consisting of Drs. Howard Morrow, San Francisco; William H. Mook, St. Louis, and Henry R. Varney, Detroit.

The following papers were read as a symposium on "Syphilis":

Dr. B. Barker Beeson, Chicago: "Polyneuritis Plus Dermatitis Exfoliativa Following Neo-Arsphenamin."

Dr. George M. Olson, Minneapolis: "Arsphenamin Dermatitis."

Drs. Harold N. Cole and Sidney Littman, Cleveland: "A Study of the Absorption of Mercury Injections by Means of the Roentgen Ray."

Dr. Paul A. O'Leary, Rochester, Minn.: "The Value of the Provocative Wassermann Test in the Diagnosis of Obscure Syphilis."

These four papers were discussed by Drs. Richard L. Sutton, Kansas City, Mo.; Arthur W. Stillians, Chicago; Augustus Ravogli, Cincinnati; Samuel E. Sweitzer, Minneapolis; William H. Mook, St. Louis; Howard Morrow, San Francisco; Ernest L. McEwen, Chicago; William Allen Pusey, Chicago; F. W. Cregor, Indianapolis; John H. Stokes, Rochester, Minn.; Walter J. Highman, New York; W. D. Calvin, Fort Wayne, Ind.; I. L. McGlasson, San Antonio, Texas; B. Barker Beeson, Chicago, and Harold N. Cole, Cleveland.

Dr. Howard Fox, New York, and D. J. Edgar Fisher, Pittsburgh, presented a paper on "Protein Sensitization in Eczema." Discussed by Drs. John H. Stokes, Rochester, Minn.; Walter J. Highman, New York, and Norman Walker, Edinburgh, Scotland.

Dr. Richard L. Sutton, Kansas City, Mo., read a paper on "Infectious Eczematoid Dermatitis." Discussed by Drs. Francis E. Senear, Chicago; Augustus Ravogli, Cincinnati; Everett S. Lain, Oklahoma City; Ernest L. McEwen, Chicago; Harold N. Cole, Cleveland; William A. Quinn, Chicago; J. N. Roussel, New Orleans; William H. Mook, St. Louis; M. J. Farber, St. Joseph, Mo., and Richard L. Sutton, Kansas City, Mo.

Drs. Jerome Kingsbury and Paul E. Bechet, New York, presented a paper entitled "Venipuncture as an Occasional Adjuvant in the Treatment of Certain Diseases of the Skin." Discussed by Drs. John H. Stokes, Rochester, Minn.; William Allen Pusey, Chicago; Augustus Ravogli, Cincinnati; F. W. Cregor, Indianapolis; Howard Fox, New York, and Paul E. Bechet, New York.

THURSDAY, APRIL 29—AFTERNOON

A joint meeting was held with the section on Pharmacology and Therapeutics. The meeting was called to order at 2 o'clock by the chairman of the Section on Dermatology and Syphilology, Dr. Oliver S. Ormsby, Chicago.

The following papers were read as a symposium on "Arsphenamin":

Dr. George W. Raiziss, Philadelphia: "The Chemical Composition of Arsphenamin and Neo-Arsphenamin and Its Relation to Toxicity."

Drs. John A. Kolcer and Baldwin Lucke, Philadelphia: "The Pathology of Arsphenamin and Neo-Arsphenamin Intoxication: An Experimental Study."

Dr. George B. Roth, Washington, D. C.: "Some Salient Facts Regarding the Toxicity of Arsphenamin and Neo-Arsphenamin."

Dr. John H. Stokes, Rochester, Minn.: "Therapeutic Applications and Limitations of the Arsphenamins."

Dr. Joseph A. Elliott, Charlotte, N. C.: "Effects of Arsphenamin on Renal Function in Syphilitic Patients."

Drs. Henry J. Nichols and Mathew A. Reasoner, Washington, D. C.: "The Use of Arsphenamin in Nonsyphilitic Diseases."

Dr. Dudley D. Stetson, New York: "Report on the Use of a Permanent Solution of Arsphenamin."

These seven papers were discussed by Drs. William Allen Pusey, Chicago; William H. Guy, Pittsburgh; Richard L. Sutton, Kansas City, Mo.; Augustus Ravogli, Cincinnati; Ernest L. McEwen, Chicago; Charles M. Williams, New York; George W. McCoy, Washington, D. C.; Harold N. Cole, Cleveland; Julius Grinker, Chicago; Alec N. Thomson, Brooklyn; J. N. Roussel, New Orleans; Marion H. Foster, Alexandria, La.; Otto Lowy, Newark, N. J.; M. J. Farber, St. Joseph, Mo.; Arthur W. Stillians, Chicago; W. D. Calvin, Fort Wayne, Ind.; Walter J. Highman, New York; Paul E. Bechet, New York; George P. Lingenfelter, Denver; Cary Eggleston, New York; W. T. Watson, Baltimore; George W. Raiziss, Philadelphia; John A. Kolcer, Philadelphia; George B. Roth, Washington, D. C.; John H. Stokes, Rochester, Minn.; Dudley D. Stetson, New York, and Major Henry J. Nichols, Washington, D. C.

FRIDAY, APRIL 30—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Oliver S. Ormsby, Chicago.

The following officers were elected for the ensuing year: chairman, Dr. Walter J. Highman, New York; vice chairman, Dr. Everett S. Lain, Oklahoma City; secretary, Dr. Harold N. Cole, Cleveland; delegate, Dr. Howard Fox, New York.

The following papers were presented as a symposium on "New Growths":

Dr. Everett S. Lain, Oklahoma City: "A Clinical Study of Epitheliomas of the Lower Lip."

Dr. Charles M. Williams, New York: "Malignant Degeneration of Benign Dermatoses."

Dr. Earl D. Crutchfield, Galveston, Texas: "Malignant Tumors of the Skin."

Dr. Erwin F. Smith, Washington, D. C.: "Production of Tumors in the Absence of Parasites."

Dr. George E. Pfahler, Philadelphia: "The Treatment of Keloid and Hypertrophied Scars by Radiotherapy Alone or Combined with Excision."

These five papers were discussed by Drs. Norman Walker, Edinburgh, Scotland; William C. MacCarty, Rochester, Minn.; John E. Lane, New Haven, Conn.; Augustus Ravogli, Cincinnati; William H. Guy, Pittsburgh; J. H. King, Nashville, Tenn.; Richard L. Sutton, Kansas City, Mo.; Harold N. Cole, Cleveland; Howard Morrow, San Francisco; George E. Pfahler, Philadelphia; Everett S. Lain, Oklahoma City; Charles M. Williams, New York; Earl D. Crutchfield, Galveston, Texas, and Erwin F. Smith, Washington, D. C.

Drs. Samuel E. Sweitzer and Henry E. Michelson, Minneapolis, presented a paper on "Acidosis in Skin Diseases." Discussed by Drs. Richard L. Sutton, Kansas City, Mo.; Augustus Ravogli, Cincinnati, and Samuel E. Sweitzer, Minneapolis.

Dr. Francis E. Senear, Chicago, read a paper on "Lichen Spinulosus and Folliculitis Decalvans: A Clinical Combination." Discussed by Drs. J. H. King, Nashville, Tenn.; F. W. Cregor, Indianapolis; Walter J. Highman, New York; Oliver S. Ormsby, Chicago, and Francis E. Senear, Chicago.

Dr. Ernest L. McEwen, Chicago, read a paper on "The Association of Herpes Zoster and Varicella." Discussed by Drs. Oliver S. Ormsby, Chicago; Everett S. Lain, Oklahoma City; George P. Lingenfelter, Denver; J. H. King, Nashville; Walter J. Highman, New York; Richard L. Sutton, Kansas City, Mo., and Ernest L. McEwen, Chicago.

Dr. Lyle B. Kingery, Ann Arbor, Mich., read a paper on "The Histogenesis of Molluscum Contagiosum." Discussed by Drs. J. H. King, Nashville; Walter J. Highman, New York, and Lyle B. Kingery, Ann Arbor, Mich.

SECTION ON UROLOGY

WEDNESDAY, APRIL 28—MORNING

The meeting was called to order at 9:20 by the chairman, Dr. William E. Lower, Cleveland.

Dr. Lower read the chairman's address, entitled "Disposition of the Ureter in Surgical Conditions of the Bladder Involving the Ureteral Orifices."

Dr. Benjamin A. Thomas, Philadelphia, read a paper on "The Treatment of Bladder Tumors with Analysis of Cases," and gave a demonstration of slides and instruments.

Drs. Walter E. Sistrunk and E. Starr Judd, Rochester, Minn., presented a paper on "Results of Surgical Treatment of Tumors of the Bladder."

These two papers were discussed by Drs. B. C. Corbus, Chicago; Victor D. Lespinasse, Chicago; Arthur B. Cecil, Los Angeles; Abraham Hyman, New York; Henry J. Scherck, St. Louis; Arthur H. Curtis, Chicago; James A. Gardner, Buffalo; Herman L. Kretschmer, Chicago; George E. Pfahler, Philadelphia; Albert E. Goldstein, Baltimore; H. W. E. Walther, New Orleans; A. J. Crowell, Charlotte, N. C.; Benjamin A. Thomas, Philadelphia, and Walter E. Sistrunk, Rochester.

Dr. Percy E. McCown, Indianapolis, read a paper on "Papillomatous Epithelioma of Kidney Pelvis." Discussed by Drs. W. F. Braasch, Rochester, Minn.; C. M. Harpster,

Toledo, Ohio; W. E. Stevens, San Francisco; Abraham Hyman, New York; Herman L. Kretschmer, Chicago; Albert E. Goldstein, Baltimore; William E. Lower, Cleveland, and Percy E. McCown, Indianapolis.

The chairman appointed Drs. Harry A. Fowler, Washington, D. C., and Courtney W. Shropshire, Birmingham, to fill the vacancies on the executive committee caused by the absence of Drs. Hugh Cabot, Ann Arbor, Mich., and Edward L. Keyes, New York.

THURSDAY, APRIL 29—MORNING

The meeting was called to order at 9:10 by the chairman.

The chairman appointed the following nominating committee: Drs. James A. Gardner, Buffalo; W. F. Braasch, Rochester, Minn., and Carl L. Wheeler, Lexington, Ky.

Dr. Arthur B. Cecil, Los Angeles, read a paper on "Abdominal Pain in Diseases of the Kidney and Ureters." Discussed by Drs. William E. Stevens, San Francisco; W. F. Braasch, Rochester, Minn.; Harry A. Fowler, Washington, D. C.; Abraham Hyman, New York; Albert E. Goldstein, Baltimore; William E. Lower, Cleveland, and Arthur B. Cecil, Los Angeles.

Drs. Herman L. Kretschmer and Henry F. Helmholtz, Chicago, presented a paper on "Studies of Pyelitis in Infancy." Discussed by Drs. W. F. Braasch, Rochester, Minn.; I. L. Van Zandt, Fort Worth, Texas; Marcell Hartwig, Los Angeles; Abraham Hyman, New York; Henry J. Scherck, St. Louis; Arthur B. Cecil, Los Angeles; William E. Stevens, San Francisco; B. C. Willis, Rocky Mount, N. C., and Herman L. Kretschmer, Chicago.

Drs. Abraham Hyman and Edwin Beer, New York, presented a paper on "Nephrectomy: Based on the Record of 250 Cases." Discussed by Dr. Arthur B. Cecil, Los Angeles.

Dr. Albert E. Goldstein, Baltimore, read a paper on "Ureteral Obstruction and Dilatation in the Male." Discussed by Drs. H. W. E. Walther, New Orleans; W. F. Braasch, Rochester, Minn.; Abraham Nelken, New Orleans; James A. Gardner, Buffalo; Herman L. Kretschmer, Chicago; C. M. Harpster, Toledo; Abraham Hyman, New York; A. J. Crowell, Charlotte, N. C., and Albert E. Goldstein, Baltimore.

Dr. William F. Braasch, Rochester, Minn., read a paper on "Occluded Renal Tuberculosis." Discussed by Drs. Joseph Hume, New Orleans; Herman L. Kretschmer, Chicago; Henry McClure Young, St. Louis; A. J. Crowell, Charlotte, N. C.; Harry A. Fowler, Washington, D. C., and W. F. Braasch, Rochester, Minn.

Dr. Ernest M. Watson, Buffalo, read a paper on "Developmental Factors in the Formation of Certain Vesical Diverticula." Discussed by Drs. Victor D. Lespinasse, Chicago; William E. Lower, Cleveland, and Ernest M. Watson, Buffalo.

FRIDAY, APRIL 30—MORNING

The meeting was called to order at 9 o'clock by the chairman.

The following officers were elected for the ensuing year: chairman, Dr. Richard F. O'Neil, Boston; vice chairman, Dr. Joseph Hume, New Orleans; secretary (for three years), Dr. Herman L. Kretschmer, Chicago; executive committee, Dr. Edward L. Keyes, Jr., New York; Dr. William F. Braasch, Rochester, Minn.; Dr. William E. Lower, Cleveland; delegate, Dr. E. O. Smith, Cincinnati; alternate, Dr. Henry G. Bugbee, New York.

Dr. James A. Gardner, Buffalo, read a paper on "Contraindications to Prostatectomy." Discussed by Drs. Herman L. Kretschmer, Chicago; Arthur B. Cecil, Los Angeles; E. G. Ballenger, Atlanta; Harry A. Fowler, Washington, D. C.; J. J. Gilbride, Philadelphia; A. J. Crowell, Charlotte, N. C.; William E. Lower, Cleveland; Victor D. Lespinasse, Chicago, and James A. Gardner, Buffalo.

Dr. Harry A. Fowler, Washington, D. C., read a paper on "Ulcer of the Bladder—Hunner Type." Discussed by Drs. Arthur B. Cecil, Los Angeles; Loyd Thompson, Hot Springs, Ark.; James A. Gardner, Buffalo; C. M. Harpster, Toledo,

Ohio; H. W. E. Walther, New Orleans, and Harry A. Fowler, Washington, D. C.

Dr. George H. Day, Louisville, read a paper on "Urologic and Venereal Idiosyncrasies in the Negro." Discussed by Drs. Thomas M. Paul, St. Joseph, Mo.; G. E. Johnson, Holly Springs, Miss., and Victor D. Lespinasse, Chicago.

Drs. William E. Stevens and Maurice Heppner, San Francisco, presented a paper on "Gonorrhea of the Lower Genito-Urinary Tract in Women, with Special Reference to the Glands of Bartholin." Discussed by Drs. E. G. Ballenger, Atlanta; Herman L. Kretschmer, Chicago; George H. Day, Louisville; Abraham Nelken, New Orleans; A. J. Crowell, Charlotte, N. C., and William E. Stevens, San Francisco.

Dr. E. G. Ballenger, Atlanta, read a paper on "Orchitis from Mumps: Conservation of the Testes by Incision of the Tunica Albuginea." Discussed by Drs. Victor D. Lespinasse, Chicago, and E. G. Ballenger, Atlanta.

Dr. Victor D. Lespinasse, Chicago, read a paper on "Spermatogenesis in Relation to Childlessness." Discussed by Drs. Albert E. Goldstein, Baltimore; A. J. Crowell, Charlotte, N. C.; and Dr. Victor D. Lespinasse, Chicago.

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, APRIL 28—AFTERNOON

The section was called to order at 2:15 by the vice chairman, Dr. Roland Hammond, Providence, R. I.

In absence of Dr. Emil S. Geist, Minneapolis, a member of the Executive Committee, Dr. Edward S. Hatch, New Orleans, was appointed by the chairman to fill Dr. Geist's place.

Dr. Frank E. Peckham, Providence, R. I., read a paper on "Orthopedic Conditions Directly Due to Sterilized Food in Infancy." Discussed by Drs. Maurice L. Blatt, Chicago; L. C. Spencer, New Orleans; Albert H. Byfield, Iowa City; Gustave Lippmann, St. Louis; J. D. Griffith, Kansas City, Mo., and Frank E. Peckham, Providence, R. I.

Dr. Leo Eloesser, San Francisco, read a paper on "Operations for Repair of Bone Defects: Results Obtained at Letterman General Hospital." Discussed by Drs. Dean F. Winn, Staten Island, N. Y.; Harry M. Sherman, San Francisco; Edwin W. Ryerson, Chicago; Frederick J. Gaenslen, Milwaukee; H. Winnett Orr, Lincoln, Neb.; Philip Lewin, Chicago; B. G. Chollett, Toledo, Ohio; Paul A. McIlhenny, New Orleans, and Leo Eloesser, San Francisco.

Dr. J. Spencer Davis, Dallas, Texas, and Jacob J. Sybenga, Pella, Iowa, presented a paper on "Results of Bone Graft at U. S. Army Hospital No. 3."

Dr. Albert H. Freiberg, Cincinnati, arose to the point of order that the demonstration was in conflict with one of the rules of the American Medical Association, in that the material presented and pictures shown have appeared in a book published by Dr. Frederick H. Albee. The chairman sustained the objection, but ruled that moving pictures of illustrative cases might be shown, any discussion to be limited to these. The film was then presented and discussed by Drs. Paul B. Magnuson, Chicago; L. C. Spencer, New Orleans; Willis C. Campbell, Memphis, Tenn., and J. Spencer Davis, Dallas, Texas.

The following papers were read as a symposium on "Treatment of Infantile Paralysis":

De Forest P. Willard, Philadelphia: "Transverse Horizontal Section of the Tarsus in Paralytic Calcaneus and Flail Foot."

H. Winnett Orr, Lincoln, Neb.: "Indications for and End-Results of Surgical Operations in Infantile Paralysis."

Frederick J. Gaenslen, Milwaukee: "Sling Suspension Method of Exercises in Infantile Paralysis."

These three papers were discussed by Drs. John D. Ridlon, Chicago; Willis K. West, Oklahoma City; Clarence W. East, Springfield, Ill.; George E. Bennett, Baltimore; Frank R. Ober, Boston; Walter G. Stern, Cleveland; Edwin W. Ryerson, Chicago; Albert H. Freiberg, Cincinnati; O. L. Miller, Atlanta, Ga.; R. W. Billington, Nashville, Tenn.; G. D. Marshall, Kokomo, Ind.; Horace R. Allen, Indianapolis;

DeForest P. Willard, Philadelphia; H. Winnett Orr, Lincoln, Neb., and Frederick J. Gaenslen, Milwaukee.

THURSDAY, APRIL 29—AFTERNOON

The section was called to order by the acting chairman at 2:15.

Dr. Wallace Blanchard, Chicago, read a paper on "Anterior Bow-Legs." Discussed by Drs. Willis C. Campbell, Memphis, Tenn., and Wallace Blanchard, Chicago.

Dr. Roland Hammond, Providence, R. I., read the chairman's address, entitled "Constructive Versus Reconstructive Surgery of the Extremities."

Dr. Robert B. Cofield, Cincinnati, read a paper on "Some of the Difficulties in the Diagnosis of Osteosarcoma." Discussed by Drs. Frederick J. Gaenslen, Milwaukee; Melvin S. Henderson, Rochester, Minn.; Harry E. Mock, Chicago; Edwin W. Ryerson, Chicago; J. D. Griffith, Kansas City, Mo.; Harry M. Sherman, San Francisco; Willis C. Campbell, Memphis, Tenn.; Robert Carothers, Cincinnati, and Robert B. Cofield, Cincinnati.

Dr. Walter G. Stern, Cleveland, read a paper on "Dislocation of the Carpal Semilunar Bone." Discussed by Drs. Edward S. Hatch, New Orleans; T. Turner Thomas, Philadelphia; DeForest P. Willard, Philadelphia; Melvin S. Henderson, Rochester, Minn., and Walter G. Stern, Cleveland.

Dr. T. Turner Thomas, Philadelphia, read a paper on "Recurrent Dislocations and Allied Chronic Conditions of the Shoulder." Discussed by Drs. Melvin S. Henderson, Rochester, Minn.; Alfred C. Wood, Philadelphia; John T. O'Ferrall, New Orleans; C. L. Storey, Detroit, and T. Turner Thomas, Philadelphia.

Dr. Albert H. Freiberg, Cincinnati, read a paper on "The Objective Symptoms of Foot Strain." Discussed by Drs. John L. Porter, Chicago; Paul B. Magnuson, Chicago, and Albert H. Freiberg, Cincinnati.

Dr. Horace R. Allen, Indianapolis, read a paper on "Unstandardized Versus Standardized Splints." Discussed by Drs. H. Winnett Orr, Lincoln, Neb.; Frank R. Ober, Boston; R. W. Billington, Nashville, Tenn.; Edwin W. Ryerson, Chicago; John Ridlon, Chicago; C. L. Storey, Detroit, and Horace R. Allen, Indianapolis.

FRIDAY, APRIL 30—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman.

The following officers were elected: chairman, Dr. Melvin S. Henderson, Rochester, Minn.; vice chairman, Dr. H. Winnett Orr, Lincoln, Neb.; secretary, Dr. Henry Bascom Thomas, Chicago (continued); delegate, Dr. John Ridlon, Chicago.

In order to have three members of the executive committee pass on the paper of Dr. Albert H. Freiberg, who is a member of that committee, the chairman appointed Dr. J. P. Lord, Omaha, to pass on this paper.

Dr. John O. Bower, Philadelphia, read a paper on "Operative Treatment of Peripheral Nerve and Associated Bone Lesions in One Stage." Discussed by Drs. Karl W. Ney, Staten Island, N. Y.; L. C. Spencer, New Orleans; Edwin W. Ryerson, Chicago, and John O. Bower, Philadelphia.

The following papers were read as a symposium on "Restoration of the Disabled."

Dr. Harry E. Mock, Chicago: "Reclamation Service for Workmen Permanently Handicapped in Industry."

Dr. Carroll L. Storey, Detroit: "Progress in the Care of Cripples."

These two papers were discussed by Drs. Alfred H. Freiberg, Cincinnati; John T. O'Ferrall, New Orleans; Frank G. Murphy, Chicago; H. Winnett Orr, Lincoln, Neb.; Clarence W. East, Springfield, Ill.; J. D. Griffith, Kansas City, Mo.; Colby W. Rucker, Washington, D. C.; Paul B. Magnuson, Chicago; J. S. Millard, Akron, Ohio; Walter G. Stern, Cleveland; Harry E. Mock, Chicago, and Carroll L. Storey, Detroit.

Dr. Robert D. Schrock, Omaha, read a paper on "Intra-Articular Fractures." Discussed by Drs. Paul A. McIlhenny,

New Orleans; Walter G. Stern, Cleveland; Albert H. Freiberg, Cincinnati; Melvin S. Henderson, Rochester, Minn.; Harry M. Sherman, San Francisco; Horace R. Allen, Indianapolis; Edwin W. Ryerson, Chicago; Willis K. West, Oklahoma City, and Robert D. Schrock, Omaha.

Dr. William L. Estes, Jr., South Bethlehem, Pa., read a paper on "The Occurrence and Causes of Functional Scoliosis in College Men." Discussed by Drs. Edwin W. Ryerson, Chicago; Melvin S. Henderson, Rochester, Minn.; Harry M. Sherman, San Francisco, and William L. Estes, Jr., South Bethlehem, Pa.

On motion, carried, a rising vote of thanks was extended to the chairman for the efficient manner in which the meeting had been conducted. Also unanimous vote of thanks was extended to the orthopedic surgeons of New Orleans for the painstaking way in which the details of social and professional entertainment had been carried out.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, APRIL 28—AFTERNOON

The meeting was called to order at 2 p. m. by the chairman, Dr. Frank Smithies, Chicago.

Dr. Frank Smithies, Chicago, read the chairman's address, entitled "The Significance of Etiologic Factors in the Treatment of Peptic Ulcer."

Drs. George Reese Satterlee, New York, and Henry A. Cotton, Trenton, N. J., presented a paper on "Fractional Gastric Analyses." Discussed by Drs. J. Rawson Pennington, Chicago; John J. Gilbride, Philadelphia; W. H. Axtell, Washington, D. C., and George Reese Satterlee, New York.

Dr. J. Rawson Pennington, Chicago, read a paper on "The Differential Diagnosis of Amebiasis, Tuberculosis, Syphilis and Carcinoma, as Manifested in the Rectum and Pelvic Colon." Discussed by Drs. W. H. Stauffer, St. Louis; Sidney K. Simon, New Orleans; Ralph W. Jackson, Fall River, Mass.; John W. Draper, New York; William M. Beach, Pittsburgh; L. J. Hirschman, Detroit, and Frank Smithies, Chicago.

Dr. Edward G. Martin, Detroit, read a paper on "Hemorrhoidectomy: Composite Operation." Discussed by Drs. James A. Duncan, Toledo, Ohio; J. Rawson Pennington, Chicago; John J. Gilbride, Philadelphia, and Edward G. Martin, Detroit.

Dr. James T. Case, Battle Creek, Mich., read a paper on "Diverticula of the Small Intestine Other than Meckel's Diverticulum." Discussed by Drs. L. T. Lewald, New York; L. J. Hirschman, Detroit; A. A. Strauss, Chicago, and James T. Case, Battle Creek, Mich.

Dr. Ernest Clyde Fishbaugh, Los Angeles, read a paper on "Hypotension Headache in Relation to Constipation." Discussed by Drs. Elsworth S. Smith, St. Louis, and Ernest Clyde Fishbaugh, Los Angeles.

Dr. M. Milton Portis, Chicago, read a paper on "Diaphragmatic Hernia Diagnosed During Life." Discussed by Drs. James T. Case, Battle Creek, Mich.; Ernest Clyde Fishbaugh, Los Angeles; W. O. Nisbet, Charlotte, N. C.; F. A. Speik, Los Angeles, and M. Milton Portis, Chicago.

THURSDAY, APRIL 29—AFTERNOON

The chairman announced the appointment of Drs. R. Walter Mills, St. Louis; H. G. Walcott, Dallas, Texas, and J. R. Pennington, Chicago, to act as a nominating committee.

The following papers were read as a symposium on "Gastric and Duodenal Ulcers":

Dr. A. C. Ivy, Chicago: "Further Studies on Gastric and Duodenal Ulcer."

Dr. Elmer L. Eggleston, Battle Creek, Mich.: "Critical Review of Five Hundred Cases of Gastric and Duodenal Ulcer."

Dr. Israel O. Palefski, New York: "Intubation and Visualization of the Duodenum with the Duodenal Tube as a Diagnostic Procedure in Duodenal Ulcer and Periduodenal Adhesions: Summary of Findings of Three Hundred and Sixty-One Established Cases."

Dr. Angelo L. Soresi, New York: "Specialization in the Medical and Surgical Treatment of Ulcer of the Stomach and Duodenum."

These four papers were discussed by Drs. A. J. Ochsner, Chicago; Charles H. Neilson, St. Louis; Sidney K. Simon, New Orleans; J. S. Horsley, Richmond, Va.; Milton M. Portis, Chicago; John J. Gilbride, Philadelphia; J. A. Storck, New Orleans; Alfred A. Strauss, Chicago; J. M. Rector, Columbus, Ohio; A. C. Ivy, Chicago; Elmer L. Eggleston, Battle Creek, Mich.; Israel O. Palefski, New York, and Angelo L. Soresi, New York.

Dr. John W. Draper, New York, read a paper on "What Is Being Done for the Insane by Means of Surgery." Discussed by Drs. A. J. Ochsner, Chicago; Robert T. Morris, New York; Henry A. Cotton, Trenton, N. J.; G. R. Satterlee, New York, and John W. Draper, New York.

FRIDAY, APRIL 30—AFTERNOON

The following officers were elected for the ensuing year: chairman, Louis J. Hirschman, Detroit; vice chairman, H. W. Soper, St. Louis; secretary, Franklin W. White, Boston; delegate, Alois B. Graham, Indianapolis; alternate delegate, Sidney K. Simon, New Orleans.

The chairman announced the appointment of Drs. Anthony Bassler, New York; William M. Beach, Pittsburgh, and Frank Smithies, Chicago, as members of the Executive Committee for the ensuing year.

Dr. William H. Stauffer, St. Louis, read a paper on "Mucous Colitis." Discussed by Drs. Bertha Van Hoosen, Chicago; H. G. Walcott, Dallas, Texas; Louis J. Hirschman, Detroit; J. Rawson Pennington, Chicago; Sidney K. Simon, New Orleans; Ralph W. Jackson, Fall River, Mass.; J. M. Rector, Columbus, Ohio; Frank Smithies, Chicago, and William H. Stauffer, St. Louis.

Dr. J. Russell Verbrycke, Jr., Washington, D. C., read a paper on "Modification of Intestinal Flora." Discussed by Drs. Frank Smithies, Chicago, and J. Russell Verbrycke, Jr., Washington, D. C.

Dr. William S. Newcomet, Philadelphia, read a paper on "Arthritic Changes in the Spine and Their Relation to the Roentgenologic Study of the Gastro-Intestinal Tract." Discussed by Drs. Julius Grinker, Chicago; E. H. Skinner, Kansas City, Mo., and William S. Newcomet, Philadelphia.

Dr. Edward H. Skinner, Kansas City, Mo., read a paper on "The Roentgenology of the Appendix: The Significance of the Opaque Filling in Chronic Appendicitis." Discussed by Drs. R. Walter Mills, St. Louis; Marsh Pitzman, St. Louis; D. F. Jones, Boston; W. H. Stewart, New York; Israel D. Palefski, New York, and Edward H. Skinner, Kansas City, Mo.

REPORT OF THE COMMITTEE ON AWARDS

Your committee recommends the following awards:

To Dr. Edmond Souchon, a gold medal, for admirably prepared anatomic specimens.

To the Medical Department, U. S. Army, a silver medal for an exhibit of pathologic preparations, excellent in appearance and highly instructive.

To Dr. Victor D. Lespinasse, a certificate of merit, for interesting and suggestive experiments on spermatogenesis and sterility.

To Dr. Martin H. Fisher, a certificate of merit for an extensive display of soap preparations in relation to colloid chemistry.

In view of the grave importance of venereal disease and the fundamental need for diffusing information regarding the dangers of these diseases to the individual and to the race, the committee wishes to commend the exhibits presented this year showing methods of sex education and to express the hope that such exhibits may be elaborated and made more prominent features of the Scientific Exhibit in the future.

W. B. CANNON,
H. H. CHRISTIAN,
E. R. LECOUNT.

REGISTRATION AT NEW ORLEANS

The total registration at the New Orleans Session was 3,681. Below are given two summaries, one by sections and one by states:

REGISTRATION BY SECTIONS

Practice of Medicine	1,160

The Digestibility of Foods.—Two factors largely determine the digestibility and absorption of foods in the process of digestion: The first is the bulk; the second is the cellulose content. The bulkiness of vegetable food interferes with digestion in two ways. The digestive juices have difficulty in penetrating such a mass so that the conversion of the constituents into products capable of absorption is apt to be quite inefficiently carried out, and the large mass has a tendency to hasten the intestinal peristalsis, the contents of the gut are thus pushed forward too rapidly; and even were digestion more complete, the absorption could not keep pace with the food movement. The presence of cellulose is the second great factor in the retardation of digestion and absorption. In the case of meat, the nutritive constituents are held in tubes composed of gelatin which readily digest; in the case of vegetables, the starch is contained in cubical compartments with walls of cellulose. Cellulose is a carbohydrate, belongs to the class of polysaccharids, and is especially characterized by its extraordinary insolubility. From this it can be seen that the presence of cellulose influences digestion and absorption in several ways. It not only has little or no food value of itself, but it prevents the access of digestive juices to the mass of food in the stomach, and it prevents the juices penetrating to the individual starch cells. Further, by increasing the mass to such an extent it has a tendency to stimulate the intestinal movements and hasten the progress of the food.—C. C. Mason, *Bull. Johns Hopkins Hosp.*, March, 1920.

TAKAKI'S WORK IN BERIBERI

The announcement of the death in Tokyo of Baron K. Takaki, former inspector general of the Japanese navy, recalls his classic experiences in eradicating beriberi among the sailors by change in diet. He had long been familiar with the disease among groups of Japanese, and he recalled that some years before he entered the navy of his country in 1872, many deaths from it had been observed by his father. Even at that time the cause of beriberi was attributed by some to food, and the provision box was called the beriberi box.¹

In his early medical experience in the navy, Takaki encountered a large number of patients suffering and dying from beriberi. In 1875 and later they frequently constituted three fourths of the whole number of persons in the naval hospital. After prolonged studies in Europe, Takaki returned to Japan in 1880 only to find conditions unchanged with respect to a scourge that threatened to destroy the efficiency of the Japanese navy. In 1883 a careful examination of the hygienic conditions of ships, barracks, schools, etc., belonging to the Japanese navy disclosed that they were much alike everywhere, except for the item of food. In this there were great variations in different places. Finding that the rations in some posts contained much carbohydrate with relatively little protein, and being of the opinion that a man requires 20 gm. of nitrogen, that is, 135 gm. of protein, a day, for proper physiologic maintenance, Takaki came to think that beriberi is caused by the disproportion of nitrogenous and non-nitrogenous components of the diet. The former were regarded as insufficient, the latter as excessive in the objectionable rations.

Takaki's proposals to change the old dietary system in which rice, rich in carbohydrate and poor in protein, predominated were regarded as extremely radical, and met great opposition. After investigation of the cruise of the training ship *Ruijo* on which 169 cases of beriberi with twenty-five deaths occurred among 276 men during 272 days, permission was granted to

institute a trial of the new ration, including milk and meat, on a cruise over the same route in the *Tsukuba*. In the course of a 287 days' voyage only four cadets and ten men were attacked by beriberi, and on investigation it was found that all of these had refused to eat certain parts of the ration provided, such as condensed milk and meat. When the good report of the experimental voyage of the *Tsukuba* became known, all opposition to the reformed ration was withdrawn, and it at once went into general effect.

The upshot of Takaki's work had been to show that although the sanitary conditions in the Japanese navy were not inferior to those in other navies at the same time, beriberi had been rampant. This disease had not broken out in ships of European nations sent to the Orient, exposed to the same climatic conditions, and performing similar duties. But the Japanese ate rice almost exclusively, omitting the bread and meat furnished to others. The diet reforms promptly produced beneficent effects. At the time referred to there were frequent objections to the validity of Takaki's theory of protein starvation as the explanation of the etiology of beriberi. This is no longer tenable in the light of recent investigations. As Vedder has stated, there cannot be a shadow of a doubt that beriberi was reduced in the Japanese navy as a result of a change of diet.

This change consisted in a reduction of the amount of rice consumed and an increase of meat, fish, vegetables, including beans, and the addition of milk and flour. What Takaki did, however, from the standpoint of present-day knowledge is to reintroduce, into a dietary largely made up of polished rice poor in antineuritic vitamin, articles of food which supply the deficiency. He neither removed a hypothetical infection, as many had contended, nor merely enriched the diet in protein; Takaki improved the physiologic quality of the ration of the navy. His experiences form an interesting chapter in the history of diet in relation to disease.

GAS CYSTS OF THE ABDOMEN

Gas cysts in the abdomen have long been known to occur in animals, particularly the hog; but it was not until 1876 that Bang published the first description of these lesions in a human being. Since that time sixty-six cases have been described in the literature, and only recently have the anatomic details been developed. The development and course of this condition are such that it may occur more often than is generally supposed. The lesions have a characteristic macroscopic appearance: Gas cysts may occur generally throughout the abdomen, multiple, disseminated, most commonly in the small intestine, mesentery and omentum, varying in size from the head of a pin to a plum, and containing an odorless, nonirritating gas

1. This and other details are quoted from Vedder, E. B.: Beriberi, New York, William Wood & Co., 1913.

made up of combinations of hydrogen, carbon, oxygen and nitrogen. Occasionally the cysts are grouped into a mass the size of a fist, causing pressure on the surrounding viscera. Palpation gives a crackling similar to that of an emphysema. The various descriptions of the size, location and character of the cysts are considered by Tuffier and Letulle¹ to be due to the fact that the observers have encountered the disease at different stages.

In the small intestine the cysts may be found in the submucous and subserous layers with a wall of dense fibroid tissue, poor in fixed cells and blood vessels, in which elastic fibers appear, but no smooth muscle. The lumen is bounded by a layer of endothelial and multinucleated giant cells, and a characteristic thick fluid is sometimes present in the dependent part of the cavity. Accompanying changes in the wall of the intestine indicate the presence of a long standing chronic inflammation. In all cases it is noted that the cysts lie in a definite relation to a lymphatic vessel which has been partially or totally obliterated.

It is this relationship of cyst, cicatrix and lymph vessel that has led Letulle,² from whose articles much of this information is taken, to the conclusion that the cysts have their origin in obstruction to the flow of lymph by a chronic obliterating lymphangitis which is a part of a rather generalized chronic inflammatory process. The origin of the gas is not so clear. At present there are two views: the one, infectious, attributing the gas to a small liquefying coccus or to *B. coli*; the other, mechanical, a complication of a chronic obliterating lymphangitis with stagnation of lymph and subsequent change to gas under pressure. The details of this transformation are not worked out, and it is far from clear why, as has been frequently observed, there is such a rapid disappearance of the cysts after the abdomen is opened; Kadyan, however, operated on the same patient three times in five months, and noticed each time a new eruption of cysts. Karsner, reporting on the pathology of Sloan's³ case, suggests that "the condition is a subacute or chronic interstitial emphysema of the gut," the gas entering from without by way of an ulcer and being carried distally by peristaltic action. However, this does not account for the presence of the gas cysts in the peritoneum and omentum.

There is no characteristic symptomatology, the condition being encountered in all cases, thus far, unexpectedly or accidentally. Gastro-intestinal disturbances, such as nausea, vomiting, diarrhea and acute intestinal obstruction, have been produced by the mechanical action of the cysts. Of the instances col-

lected by Lenormant,⁴ twenty-one were diagnosed at necropsy and thirty-six at operation, and it is the belief of Moreau⁵ that only through the use of the roentgen ray can the condition be identified before operation.

It is interesting to note that frequently this disease is associated with other lesions of the gastro-intestinal tract, particularly ulcer of the stomach. There are, of course, many questions in regard to gas cysts not yet explained, but the condition should be recognized more often in this country. It appears that three cases have been reported.⁶

THE MECHANISM OF RECOVERY FROM LOBAR PNEUMONIA

A perusal of the medical literature of only a few years ago in comparison with present-day writings on the subject of pneumonia will give convincing evidence of the marked strides that have been made in the recent study of this important malady. Lately it has been the etiologic classification of the disease types that has been foremost in the consideration of clinicians. This, of course, has involved a better understanding of the bacteriology of pneumonia, on the one hand, and an investigation of corresponding therapeutic or prophylactic measures, on the other. Pneumonia has been produced experimentally in animals by the introduction of pure bacterial cultures into the bronchi. Although much has been learned from such studies, they have not been conclusive in their applicability to the conditions observed in the disease of man.

A review of the present status of studies in experimental pneumonia, recently published in THE JOURNAL,⁶ indicates that lobar pneumonia is bronchiogenic in character. Invasion of the blood stream by pneumococci is secondary to the introduction of the micro-organisms into the lower respiratory tract. A true lobar pneumonia cannot be produced by subcutaneous or even intravenous introduction of the pneumococcus into the system, although a septicemia may develop under such circumstances. In their studies of the disease in monkeys, Blake and Cecil⁷ have observed pneumococcus septicemia persisting after the pneumonia crisis and resolution; likewise cases of unresolved pneumonia in which the pneumococci had entirely disappeared from the blood yet which resulted in death.

Such experiences have suggested that more than one factor may be involved in the mechanism of recovery from lobar pneumonia. In the escape from the general

infection an immunity mechanism of a humoral sort is undoubtedly involved. The possible rôle of circulating antibodies is admitted. But as the prevention or termination of the general infection does not always coincide with recovery from the local processes with resolution of the pneumonic consolidation, it seems highly probable that the latter may depend in part at least on something other than humoral immunity—than antibodies. Perhaps, as Blake and Cecil propose, the crisis and resolution of the pneumonic process may be due to local biochemical changes in the course of which, as suggested by Lord,⁸ the acid death point of the pneumococcus is reached. If so, final recovery from lobar pneumonia may involve a dual mechanism, and future considerations of the problem must keep the possible significance of the two factors distinctly in mind. One concerns most directly the local pulmonary lesion; the other is important as well for the secondary general infection by the pneumococcus.

Current Comment

DUST AND PHTHISIS

Dust inhaled is popularly regarded as a source of danger to the organism, particularly by predisposing to pulmonary tuberculosis. Experience has demonstrated, however, that not all dusts are to be put into a common category. If there are no benevolent dusts, some at least seem to be far less deadly than others, although all forms of them enter the lungs. Investigations made in South Africa have demonstrated, for example, that a condition known as pneumoconiosis results from dust particles setting up cell proliferation which ends in the production of dense connective tissue. The latter occurs first in nodules which may subsequently coalesce, obliterating large portions of air-containing vesicles. Sufferers from this condition are peculiarly liable to pulmonary tuberculosis, as miner's phthisis and potter's rot. Some dusts, notably soot and coal dust, appear, however, to be comparatively harmless. An attempt to explain this has been made by Mavrogordato⁹ in a report to the British Medical Research Committee in London. It appears that marked differences appear in the readiness with which different kinds of dust are eliminated from the lung tissue. Some produce a marked initial reaction, with much shedding of epithelium. In these shed cells, coal and shale are promptly removed, so that they do not set up processes which block the lymphatics. On the other hand, flue dusts and silica are taken up by cells which tend to remain in situ and form plaques which appear early and persist. They become the sites of fibrosis. From the current investigations it further appears that dusts, like coal, which produce an initial reaction tend to carry out with them the more inert kinds of particles. The dusts which make most mis-

chief appear to be those tending to accumulate rather than to be promptly eliminated. Corper¹⁰ has found a correlation between these facts and the effect of lamp black and pulverized glass, respectively, on the acceleration of experimental tuberculosis in the guinea-pig. Glass, which resembled the quartz dusts, had a markedly accelerating influence, whereas the carbon particles likewise injected subcutaneously coincident with tubercle bacilli exhibited a retarding effect. Whether this beneficent outcome is due to some inherent antiseptic property introduced with the coal or soot or to a biologic reaction cannot be stated at present. However, the facts help to explain why "phthisis is not as common among coal miners as among the ordinary population in spite of the marked amount of anthracosis developed in the lungs from the inhaled dust."

COUNTING BLOOD PLATELETS

To most physicians the blood platelets are known merely as structural elements present along with the familiar erythrocytes and leukocytes in the blood. Beyond this, the existence of these somewhat irregular particles carries no special significance to most clinicians not specially trained in the methods of hematology. This is doubtless due in large measure to the difficulties that have attended the accurate estimation of the occurrence of the platelets in specimens of blood, as well as to the lack of knowledge which still enshrouds their origin, fate and functions. The content of the other formed elements or corpuscles of the blood is now readily ascertained with considerable exactness, and the significance of high or low "counts" in relation to various pathologic conditions is well understood. It is not surprising, however, that confusion and uncertainty exists in the case of the platelets; for at present the statements as to their normal occurrence in blood show figures varying as much as 300 to 400 per cent., namely, from 200,000 to 800,000 per cubic millimeter of blood. Part of the difficulty thus recorded is attributable to the labile character of these structures. Unless specially conserved, they disintegrate with great readiness in shed blood. The actual counting of the "third corpuscular elements" of the blood has encountered additional obstacles, which need not be recounted here. Lately a new technic, developed by Thomsen¹¹ for counting the platelets in citrated plasma has been made the subject of special investigation by Gram¹² in Faber's clinic at Copenhagen. The method appears to be more reliable than any other at present in vogue; by it the majority of the determinations show platelet counts between 300,000 and 450,000 per cubic millimeter. Although in normal persons the number rarely falls below 300,000, the more extreme range for seemingly healthy persons may be put at from 200,000 to 500,000 per cubic millimeter of blood. There have been frequent attempts in the past to correlate aberrant platelet counts with hemorrhagic diseases of various types.

9. Mavrogordato, A.: Experiments on the Effects of Dust Inhalations, *J. Hyg.* 17: 439 (Oct.) 1918.

Thus, the platelets have long been assumed to be associated in some way with the clotting of the blood. Gram has observed, in accord with this, that when the platelet count falls below 100,000 per cubic millimeter the "bleeding time," determined by Duke's well known method, tends to be prolonged; that is, the blood clots more slowly than usual. The platelets are diminished in number in pernicious anemia, in most cases of lymphatic leukemia, and in some cases of myeloid leukemia. Normal values are found in hemophilia, and augmented values are found in many cases of simple anemia and some of myeloid leukemia. According to Gram, the counting of the platelets and determination of the bleeding time is of extreme importance as a preoperative measure, especially in cases of aplastic anemia, in which an operation often is performed for explorative purposes, on suspicion of occult cancer.

CALCIUM METABOLISM IN LEPROSY

Destructive processes of various sorts are sequelae of leprosy invasion of the body. Among such changes, necrosis resulting in the loss of pieces of bone and atrophy of osseous structures may occur. The consequences are exhibited in the altered mineral metabolism observed in leprosy, as has recently been demonstrated by Underhill, Honeij and Bogert¹ in an unusually elaborate series of examinations on leprosy patients at the Yale University School of Medicine. Compared to normal persons under the same dietary conditions, such patients retain calcium in relatively large quantities, whether they are maintained on a calcium-poor or a calcium-rich diet; and the greater the intake of calcium, the greater is the relative retention. In the more advanced stage of the disease, the degree of retention is greater than in the early phase. There is likewise a positive balance in the case of magnesium in the advanced stages of leprosy, although the retention of this element is much less marked than that of the more conspicuous bone-forming calcium. According to Underhill and his colleagues, the retention of calcium is the expression of a metabolic demand—a need induced by the loss of bone-salt in the disease. Hence they suggest that quite likely in dietary conditions in which calcium is not particularly abundant, the lack of this element may be an important factor in the rapidity of the progress of the disease; for this may be greatly retarded, or perhaps even alleviated, if an abundance of calcium is present in the diet.

CHIROPRACTIC—LUX ON SUBLUXATIONS

Members of the medical profession have long been at a loss to know just what "chiropractic" is. They know what "chiropractors" are, but "chiropractic"—that has been a mystery! It remained for the Senate and General Assembly of the State of New Jersey to elucidate. An Act to Regulate the Practice of Chiropractic recently signed by the Governor of New

Jersey gives to a palpitating medical world this vital information. Here is the opening paragraph of the act:

DEFINITION OF CHIROPRACTIC: The term chiropractic when used in this act shall be construed to mean and be the name given to the study and application of a universal philosophy of biology, theology, theosophy, health, disease, death, the science of the cause of disease and art of permitting the restoration of the triune relationships between all attributes necessary to normal composite forms, to harmonious quantities and qualities by placing in juxtaposition the abnormal concrete positions of definite mechanical portions with each other by hand, thus correcting all subluxations of the articulations of the spinal column, for the purpose of permitting the recreation of all normal cyclic currents through nerves that were formerly not permitted to be transmitted, through impingement, but have now assumed their normal size and capacity for conduction as they emanate through intervertebral foramina—the expressions of which were formerly excessive or partially lacking—named disease.

Lucidity itself! The New Jersey legislature said, "Let there be light on Chiropractic"—and, behold, it became the "art of permitting the restoration of the triune relationships between all attributes necessary to normal composite forms, to harmonious quantities and qualities . . ." Simplicity to the *n*th power. Bring on your Einstein theory—the New Jersey solons may oblige with a snappy definition.

ENFORCED TEMPERANCE IN EUROPE

The advocates of prohibition are already beginning to marshal statistics as to the result of the abolition of the liquor traffic on the welfare of the nation. It will not be easy to establish the relation of cause and effect in the various phenomena of change in which benefit or disadvantage may be claimed. The altered social and economic conditions following the war have brought about new conditions of living and standards of conduct the precise effect of which on the people of the United States remains to be clearly ascertained. However, in the matter of restriction of the consumption of alcohol, if not its entire prohibition, this country has not stood entirely alone in recent years. During the war our allies and the enemy country restricted the manufacture of alcoholic beverages; and the neutrals surrounding the Central Empires did likewise. A curtailment has, moreover, followed not only through legal restrictions on sales which confined public drinking to certain hours and places, but also as the direct result of scarcity and high prices which made purchases difficult. This has been particularly true of the strongly alcoholic beverages, like brandy. The benefits of temperance to the thousands of men in the armies can scarcely be debated. An elaborate investigation made by a commission of scientists and clinicians for the German government and published in 1919¹ affords interesting conclusions for the civilian population of a country accustomed to liberal indulgence in alcoholic drinks. It appears, particularly

1. Underhill, F. P.; Honeij J. A., and Bogert, L. J.: Calcium and Magnesium Metabolism in Certain Diseases, *Proc. Nat. Acad. Sc.* 6:79 (Feb.) 1920.

1. Welchen Einfluss hat der während des Krieges innerhalb der bürgerlichen Bevölkerung verminderte Alkoholgenuss auf die geistige und körperliche Gesundheit des Volkes gehabt? Beratung der erweiterten Wissenschaftlichen Deputation für das Medizinalwesen am 20 September, 1919, im Ministerium für Volkswohlfahrt zu Berlin, *Vrtljschr. f. gerichtl. Med.* 59:1 (Jan.) 1920.

from the report of Professor Partsch, that in Prussia, as a result of restricted drinking, there was an extraordinary decrease of chronic alcoholism and the mental disorders attendant on it. Related bodily illnesses were also diminished. The decrease in psychic maladies was widespread, not being confined to any portion of the empire. The report finds special occasion to note the restoration of former chronic drunkards in many cases to an economically useful career. Contrary to what is alleged by some of the defenders of alcohol in this country—on what basis we do not know—the habitual use of morphin or cocain is not interpreted by the Prussian medical commission as the outcome of restriction in the availability of alcohol. It insists that the desire for strong alcoholic stimulants among the population has by no means become suppressed. Only the excessive cost and the restricted supplies are believed to stand in the way of a return to former habits, now that peacetime conditions are being restored abroad. If temperance enforced by the exigencies of a war has in truth exercised a highly beneficent influence on the nations, the problem of retaining its essential benefits is surely one worthy of consideration in any propaganda for the public health.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

University of Southern California Suspends Medical Teaching.—By a unanimous vote, the trustees of the University of Southern California, on April 13, decided to temporarily suspend the medical department because of inadequate endowment with which to maintain it.

Botulism a Reportable Disease.—Under date of April 9, the secretary of the state board of health issued a bulletin declaring botulism a reportable disease, and requesting physicians to make prompt reports of this disease to the local health officers and asking also that information be sent concerning probable causative food factors.

Personal.—Dr. Albrecht O. Eckardt, Downieville, health officer of Sierra County for several years, has been appointed resident physician for the Claymath Indian Reservation with headquarters near Claymath Falls.—Dr. Frank P. Gray, G. M. Stratton and Dr. Emanuel C. Fleischner of the faculty of the University of California have been given leave of absence for portions of this and next year.

San Francisco Physicians to Fight Medical Law Changes.—At a meeting of the San Francisco County Medical Association, held April 13, plans were made to fight, in the coming general election, the following issues which the organization considers would be letting down the bars to unscientific systems of medicine: an initiative measure to establish an independent board of chiropractic examiners; referendum on the drug law to give osteopaths the right to prescribe drugs; antivivisection legislation, and efforts to lower medical certificate requisites.

DISTRICT OF COLUMBIA

Gift for Howard Medical School.—It is announced that Howard University School of Medicine, Washington, has been promised \$250,000 by the general education board, provided the medical school succeeds in raising the rest of a total sum of \$500,000.

Medical Society Against Unlicensed Anesthetists.—At a recent largely attended meeting of the Medical Society of

the District of Columbia a resolution was adopted after animated debate putting the society on record as in favor of the limitation of the practice of anesthesia to regularly licensed physicians and surgeons and dentists, and graduate nurses in cases of emergency or medical students for purposes of instruction. This action was prompted by the recent substitution in certain of the local hospitals of salaried resident anesthetists for the physician anesthetists connected with the medical staff, the new appointees being nurses specially trained in anesthesia work.

Cornerstone Laid of Medical Society Building.—On May 6 the cornerstone of the new home of the Medical Society of the District of Columbia was laid. The ceremonies were presided over by Dr. Charles W. Richardson, the stone being laid by the officers of the society, the president, Dr. Francis R. Hagner, spreading the mortar. Addresses were made by Dr. Hagner, Dr. Wilfred M. Barton, Dr. Joseph S. Wall and Dr. John B. Nichols. Dr. Tom A. Williams also made a short address in presentation of a handsome donation from a friend whom he had interested in the project. The building is located at 1716-1718 M Street N.W. It is hoped that it will be ready for occupancy in November. When complete, the medical society will possess a handsome, commodious and comfortable home, which will also be a distinct addition to the architectural beauties of Washington.

ILLINOIS

Tuberculosis Clinics.—The second of the series of free tuberculosis clinics will be held at the court house, Edwardsville, May 26, under the auspices of the Madison County Medical Society. Dr. George T. Palmer, Springfield, will be in charge of the clinic.

Sanatorium Opened.—Adams County has recently opened a tuberculosis sanatorium at Quincy with a capacity of twenty-five patients. It is under the charge of Dr. Harry C. Worthington, formerly senior physician to the Cook County Tuberculosis Hospital, Oak Forest.

Tri-City Officers Elected.—The Tri-City Medical Society held its annual meeting, April 15, and elected Dr. Benjamin H. King, president; Dr. Alfred E. Everett, vice president; Dr. Hugo C. H. Schroeder, secretary, and Dr. Frank O. Johnson, treasurer, all of Granite City.

Chicago

Hospital Journal Moves.—The *Modern Hospital* has announced the removal of its editorial and business offices to the Modern Hospital Building, 22-24 East Ontario Street.

Ricketts Prize Awarded.—The Howard Taylor Ricketts Prize of the University of Chicago for 1920 has been awarded to Ivan C. Hall for his work on "Studies in Anaerobiology." This prize is awarded annually on May 3, the anniversary of the death of Dr. Ricketts from typhus fever, while engaged in work on this disease in Mexico City in 1910.

Anthrax Outbreak.—Six cases of anthrax were reported during the first week in May with five deaths. The disease is believed to have been contracted through infected horse hair received from Russia and Argentina, last winter. The Chicago Curled Hair Factory, among the employees of which this disease occurred, was closed by the health department, May 5.

INDIANA

Personal.—Dr. Carleton B. McCulloch, Indianapolis, was nominated for governor on the democratic ticket at the primary election, May 4.—Drs. Charles B. Kern, Lafayette, and John H. Hewitt, Terre Haute, have been reappointed members of the state board of health.—Dr. Obediah H. Garrett, Cadiz, is seriously ill as the result of a cerebral hemorrhage.—Dr. George A. Harrop, Jr., South Bend, has been awarded a traveling fellowship for the study of physiology in Denmark.

Hospital Items.—Shelbyville is to have a new hospital which is estimated to cost \$225,000. A site for the building was recently purchased for \$11,000. The institution will have accommodation for fifty patients.—A memorial hospital is to be established at Jeffersonville in honor of the soldier dead of Clark County.—Home Hospital, Muncie, is to be transferred to the board of governors, who will operate it as a public health hospital.—The Indiana Manufacturers' Reciprocal Association will establish in Indianapolis a physiotherapy hospital wherein workmen injured in industries in the factories of the association are to be rehabilitated to a degree that will allow them to reenter their fields of

labor.—The county board of Allen County has decided to build an addition to the County Isolation Hospital sufficient to offer at least temporary relief during the present prevalence of scarlet fever in Fort Wayne.

LOUISIANA

Personal.—Dr. Mayer A. Newhauser, Shreveport, has resigned as assistant health officer.—Dr. Sidney L. Williams has resigned as a member of the Shreveport Board of Health.

State Society Election.—At the annual meeting of the Louisiana State Medical Association held in New Orleans, April 27, the following officers were elected: president, Dr. Homer J. Dupuy, Jr., New Orleans; vice presidents, Drs. Beverly W. Smith, Franklin, William H. Harris, New Orleans, and Daniel O. Willis, Leesville; secretary-treasurer, Dr. Paul T. Talbot, New Orleans, and councilors—first district, Dr. Paul Gelpi, Jr., New Orleans; second district, Dr. George S. Bel, New Orleans; third district, Dr. Frank T. Gouaux, Lockport; fourth district, Dr. Joseph E. Knighton, Shreveport, and fifth district, Dr. Thomas E. Wright, Monroe.

MARYLAND

New Officers.—At the annual meeting of the Cecil County Medical Society, Dr. Vernon H. McKnight, North East, was elected president and Dr. Howard Bratton, Elkton, secretary-treasurer.

Health of Schoolchildren in Maryland.—In response to a request from the state and local health and educational authorities, the Public Health Service is conducting a survey and demonstration concerning the health of schoolchildren in Cecil County, Maryland.

Personal.—A portrait of Dr. William H. Welch, president of the University Club of Baltimore, was presented to the club recently at its monthly meeting. A large gathering of club members and friends of Dr. Welch witnessed the presentation. Dr. William S. Baer, chairman of the committee in charge of the presentation, presided.—Dr. Otis M. Linthicum has been elected mayor of Rockville, Md.

Medical Faculty to Convene.—The Medical and Chirurgical Faculty of Maryland will hold its one hundred and twenty-second annual meeting, May 11, 12 and 13, at the faculty building, Baltimore, under the presidency of Dr. John Ruhrah, Baltimore. A session of delegates at Osler Hall will open the program, which includes scientific meetings, clinics at various hospitals and the annual smoker of the organization.

Medical Society at Johns Hopkins.—Members of the William Pepper Medical Society of the Medical Department of the University of Pennsylvania came to Baltimore, May 8, and, conducted by members of the Johns Hopkins Medical Society, visited the School of Hygiene and Public Health, the Johns Hopkins Hospital and the Johns Hopkins University. Addresses by the most prominent physicians connected with the hospital were made both at the School of Hygiene and in the amphitheater of the surgical building, Johns Hopkins Hospital. Luncheon was served on the top floor of the Phipps Psychiatric Clinic, and in the evening an informal smoker was held at the home of Dr. Joseph Colt Bloodgood, Roland Park.

Fort McHenry for Federal Hospital.—The War Department has definitely announced that U. S. General Hospital No. 2, at Fort McHenry, will be turned over to the U. S. Public Health Service for its war risk insurance work, as soon as the hospital buildings are given up by the Medical Corps of the Army. Owing to the great need of caring for the sick and disabled discharged soldiers, the War Department has transferred this post to the Public Health Service for this purpose, and at the same time has informed the special committee appointed by the mayor of Baltimore City, that the post could not be used as a municipal hospital, since by act of Congress, it was stipulated that it should be used only as a public park by Baltimore City.

MICHIGAN

Personal.—Dr. Frederick G. Novy, Ann Arbor, has been elected a corresponding member of the Society of Biology of Paris, and an associate member of the Royal Society of Medical and Natural Sciences, Brussels.

Increase in Smallpox.—During the week, ended May 1, sixty-one new cases of smallpox were reported in Detroit, an increase of twenty-eight over the previous week. Of the

cases thus far reported sixty-seven have been among the white population, and thirty-one among the colored population of the city.

MINNESOTA

Southern Minnesota Physicians to Meet.—The midsummer meeting of the Southern Minnesota Medical Association will be held in Fairmont, June 28 and 29. Dr. Walter J. Richardson is chairman of the committee of arrangements.

Clinic Week in Minneapolis.—More than 500 physicians attended the third annual clinic of the Hennepin County Medical Society, April 20 to 23. During those days clinics were conducted in all hospitals in Minneapolis, illustrated lectures were given in the afternoons and special meetings were held in the evenings. Dr. Charles Harrison Frazier, Philadelphia, at the annual banquet, April 20, delivered an address on "Surgery of the Nervous System."

Enrolment in Mayo Foundation.—During the current quarter which began April 1, 151 graduate students have been registered in the Mayo Foundation for Medical Education and Research, Rochester. Each of these students is registered for a period of three years or more. The fellows, 130 in number, are distributed as follows: surgery, 86; internal medicine, 20; otolaryngology and rhinology, 7; urology, 5; ophthalmology, 4; pathology and dermatology, each 2, and chemistry, bacteriology, roentgenology and orthopedics, each 1. Among the scholars who are not candidates for advanced degrees are 10 in surgery; 4, in dental surgery; 2, in orthopedics; and one each in roentgenology, internal medicine, dermatology, urology, and otolaryngology and rhinology.

MISSOURI

Brooklyn Physician in Kansas City.—At the meeting of the Jackson County Medical Society, May 4, Dr. John Osborn Polak, Brooklyn, delivered an address on "Present Day Operative Procedures in Obstetrics," illustrated with lantern slides.

Personal.—Dr. Ersel M. Fessenden has been appointed first house surgeon of the Frisco Hospital, Springfield, succeeding Dr. J. Omar Moore, resigned.—Dr. Roche W. Hogeboom has been appointed assistant consulting surgeon of the Frisco Hospital, Springfield.—Dr. Abraham Sophian, Kansas City, has been presented with a house and grounds valued at \$82,000 in appreciation of medical services rendered to the wife of the donor.—Dr. Hasbrouck DeLamater, St. Joseph, has been appointed health officer of Norfolk County, Va.

To Increase Salaries at St. Louis University.—This month the alumni and friends of St. Louis University launch a movement to provide the institution with an endowment fund of \$2,000,000 in commemoration of its first century of service in higher learning. The income on one half of the fund sought will be used to increase the salaries of teachers in the schools of medicine, dentistry, commerce and finance and the institute of law. For the provision of a laboratory for the school of medicine, a fund of \$250,000 is to be provided; and after these immediate needs have been cared for, a total of \$550,000 of the fund will be used to establish new clinics and to erect new buildings for the schools of medicine and dentistry. The St. Louis University opened its first school of medicine in 1836, four years after the institution received its charter. The school has been running with annual deficits for the last five years, the largest being for the school year ended in June, 1919, when the expenditures exceeded the receipts by more than \$20,000.

NEW JERSEY

Society to Meet.—The one hundred and fifty-fourth annual meeting of the Medical Society of New Jersey will be held in New Monmouth Hotel at Spring Lake, June 15 to 17, under the presidency of Dr. Gordon K. Dickinson, Jersey City.

Personal.—Dr. William J. Chandler, South Orange, secretary of the Medical Society of New Jersey, who met with a serious accident recently, is now reported to be convalescent.—Dr. Thomas W. Harvey, Orange, after thirty-eight years' service as attending surgeon at the Orange Memorial Hospital, has resigned and has been succeeded by Dr. Douglas A. Cater of East Orange. Dr. Ralph H. Hunt, East Orange, has been appointed attending physician to the hospital.—Dr. M. Charles Mackin, assistant superintendent of the New Jersey Institution for Feeble-minded, Skillman, has been appointed superintendent of the Mount Pleasant, Iowa, State Hospital, succeeding Dr. Charles F. Applegate.

NEW YORK

Health Council for Albany.—Representatives of the ten official and volunteer health agencies of Albany and vicinity have organized a health council for the purpose of securing better coordination in health work. Other organizations having health affiliations will be invited to join. Mr. Edward H. Huyck has been elected chairman; Miss Gertrude J. Owen, corresponding secretary, and Mr. Lewis R. Screenley, recording secretary.

Personal.—Dr. Harold W. Lyall, for nine months bacteriologist on the staff of the state laboratory, has accepted the position of bacteriologist of the Mellen Research Laboratories, Tuberculosis League, Pittsburgh, and of associate in the department of bacteriology and pathology in the Medical School of the University of Pennsylvania.—Miss Pearl L. Kendrick, a member of the state laboratory staff, has resigned to accept a position in the laboratory of the state department of health of Michigan.—Dr. Charles A. Howland, Schenectady, for eight and one-half years assistant sanitary engineer of the division of sanitary engineering, has resigned to accept a position in Kansas City.

Mental Clinics.—The scope of the mental clinics conducted by state hospitals in the Psychopathic Institute, under the auspices of the state hospital commission, has been enlarged during the last year to include mental defectives. Physicians as well as psychometric testers for the mentally defective patients have been supplied by the state commission, for mental defectives and the various state schools for mental defectives. These mental clinics are held whenever possible in connection with the health center established by the state department of health and in the same location with such other clinics as those for children's diseases, tuberculosis and venereal disease. The seven state departments represented by the committee on joint clinics are working in harmony with the result that extra-institutional treatment in mental and other types of cases is increasing in a very encouraging manner. These clinics are being held at all state hospitals.

New York City

Society for Clinical Study.—The next monthly meeting of the Society for Clinical Study will be held in the reception hall of the New York Diagnostic Clinic, 125 West Twenty-Second Street, on the evening of May 26.

West Side Dispensary Buys Site.—The West Side Dispensary and Hospital has purchased the property adjoining its present building as a site for a lying-in hospital. The property was purchased for \$50,000 and will be rebuilt next fall at a cost of between \$50,000 and \$100,000.

Health Department Night.—At the regular monthly meeting of the Academy of Pathological Science, April 23, the program consisted of papers on public health topics only, presented by officials of the department of health. These included: "Activities of the Board of Health"; "Schick Tests"; "Industrial Medicine"; "Food and Drug Control," and "Narcotic Addiction Medical Treatment."

Federal Government to Buy Quarantine Station.—The House of Representatives has approved the Magee bill providing for the taking over by the federal government of the quarantine station in New York Harbor. The purchase price is \$1,395,275, which is the amount settled on in condemnation proceedings. No trouble is anticipated in passing the bill through the Senate.

Grand Jury Acts on Dr. Markoe Assassination.—The grand jury sitting on the death of Dr. Markoe, who was killed in St. George's Church on April 18, suggests that a petty jury at a trial be permitted to find a defendant "guilty but insane." At present the verdict must be worded "not guilty, but insane." It suggests also that the law be amended so that a corps of physicians or neurologists be appointed as the only competent authority to certify to the court on insanity cases.

Personal.—Dr. Royal S. Copeland, health commissioner, will sail, May 8, to represent the city of New York at the Congress of the Royal Institute of Public Health, which opens in Brussels on May 19. In response to an invitation from the institute, he will deliver an address on the prevention of epidemics. He will also make a tour of European ports to study public health conditions.—Dr. John F. Ferguson has been appointed a member of the board of education.—Dr. John J. Kindred, Astoria, has been appointed highway commissioner of Queens, succeeding Mr. George Howland Leavitt.

Memorial to Dr. Jacobi.—The stated meeting of the New York Academy of Medicine of May 6 was held in memory of the late Dr. Abraham Jacobi. This date being the anniversary of Dr. Jacobi's birth was made the occasion for the presentation by his family of a bronze bas-relief of Dr. Jacobi, the one presented to him some years ago by the New York State Medical Society. The presentation was made by Hon. George McAneny, his son-in-law, and was formally accepted by Dr. George David Stewart, president of the academy. In his address Dr. Stewart reviewed the services of Dr. Jacobi to the academy during his sixty years of membership. Dr. George E. Vincent, president of the Rockefeller Foundation, delivered an address on "The Life and Influence of Dr. Jacobi Upon His Time," in which he dwelt on Dr. Jacobi's contributions to the advancement of medical science, and his clear vision of the larger possibilities of the profession.

OREGON

Personal.—Dr. Lloyd W. Brooke, Portland, after work in France and Belgium during the war has been sent to Tirana, Albania, to establish an American Red Cross dispensary.

Public Health Association Organized.—Hood River County is the seventh in the state to organize a public health association. This organization was perfected March 17 at Hood River and officers and district chairmen elected.

Botulism Reportable.—The state board of health has included botulism in its list of communicable diseases and has circularized health officers and physicians, directing attention to the importance of reporting the occurrence of any cases and of giving information regarding the suspected cause.

PENNSYLVANIA

Philadelphia

Meeting of College of Physicians.—The section on general medicine of the College of Physicians of Philadelphia held its stated meeting, April 26, at which cardiac arrhythmias were discussed, the formal presentation of the subject being by Prof. Bernard S. Oppenheimer, assistant professor of clinical medicine in Columbia University.

Personal.—Dr. Charles E. De Medici Sajous has been named in the list of nominations for the Hall of Fame in New York University.—Dr. Lawrence F. Flick has received the Laetare Medal, the highest distinction that can be conferred on a Catholic layman in the United States, awarded annually by the University of Notre Dame, as a tribute to his work in the field of medicine.—Dr. Alexander Hugh F. Barbour, M.D., LL.D., vice president of the Royal College of Physicians, Edinburgh, Scotland, addressed the Obstetrical Society of Philadelphia, May 6, on "Reminiscence and Forecast."—At the stated meeting of the College of Physicians, May 5, Dr. George H. Whipple, professor of research medicine, University of California, and Drs. Francis Peyton Rous and Philip D. McMaster of the Rockefeller Institute, read papers.

Public Health Day.—Wednesday, May 12, 1920, was made public health day for Philadelphia. The following organizations cooperated: the Philadelphia County Medical Society, the College of Physicians, the city departments of public health and public welfare, the board of public education, Children's Playground Association, the Child Federation, City Parks Association, the Civic Club, the City Club, Philadelphia Housing Association and the Pennsylvania Society for the Prevention of Tuberculosis. Short addresses on health and hygiene were made in the public and parochial schools in the morning, and in the evening many community meetings in schoolhouses and recreation centers were addressed by physicians and other qualified speakers interested in the movement. The central and most important event was the joint meeting under the auspices of the county medical society and the associated organizations and departments named above at the Manufacturer's Club.

WEST VIRGINIA

State Society Meeting.—The annual meeting of the West Virginia State Medical Association will be held in Parkersburg, May 18 to 20, under the presidency of Dr. Henry R. Johnson, Fairmont.

Public Health Service Makes Dental Survey.—In cooperation with the state board of health, the Oral Hygiene Unit of the Public Health Service is making a state-wide survey

of dental hygiene problems in West Virginia, with special reference to schoolchildren. The unit is visiting every county seat in the state and making inspections of the mouths of a number of children attending school, demonstrating to the community the extent of the dental needs of the school population, and assisting the local communities in perfecting measures whereby dental services can be provided when such do not now exist. At the same time teachers are being instructed in the principles of dental prophylaxis. Eventually it is hoped to have the proper authorities establish a mobile dental clinic to visit the schools throughout the state.

WISCONSIN

Resignations from Faculty.—It is reported that Drs. Louis M. Warfield, Charles H. Stoddard, Arthur J. Patek, Carl H. Davis and James D. Madison have resigned from the faculty of Marquette University School of Medicine, Milwaukee, on account, it is said, of a difference of opinion on the university's theory that the life of the infant must be saved before that of the mother.

Personal.—Dr. Deno F. O'Connor, Verona, who was attached to the staff of Mercy Hospital, Chicago, and later was on duty with the Semenoff forces in Siberia has been detailed as surgeon to the steamer *President Grant*, by the American Red Cross, to accompany a number of Czechoslovaks to Prague.—Dr. Herbert E. Ellsworth has been reappointed health officer of Appleton.

Clinic in Oshkosh.—A tuberculosis clinic was opened at Oshkosh, April 9 and 10, under the auspices of the Wisconsin Antituberculosis Association, under the charge of Drs. Arehm A. Pleyte, Delafield; Robert L. Williams, Statesan, superintendent of the State Tuberculosis Sanatorium, Wales; Dr. William J. Clancy, Wauwatosa, assistant medical director of Muirdale Sanatorium; Dr. Oscar Lotz, Milwaukee, and Dr. J. Gurney Taylor, Milwaukee.

CANADA

Personal.—Dr. Delmer A. Craig, formerly medical superintendent of the Alexandria Sanatorium, London, Ont., and later consultant in diseases of the chest, Military District No. 1, has accepted the position of medical consultant on the staff of the Massachusetts-Halifax Health Commission, with headquarters at Halifax.

Returned Soldiers Under Treatment for Tuberculosis.—According to an announcement in the House of Commons a few days ago, there are 1,715 returned soldiers in Canada undergoing treatment for tuberculosis. Fifteen per cent. of these are considered incurable. The total number of ex-soldiers treated in sanatoriums by provinces are as follows: Ontario, 3,404; Quebec, 1,350; Prince Edward Island and Nova Scotia, 1,126; Manitoba, 687; Saskatchewan, 445; Alberta, 275; British Columbia, 735, and New Brunswick, 272.

GENERAL

Tropical Medicine Society Meeting.—At the annual meeting of the American Society of Tropical Medicine held in New Orleans, April 27, the following officers were elected: president, Dr. John M. Swan, Rochester, N. Y.; vice presidents, Drs. Karl F. Meyer, San Francisco, and Victor G. Heiser, New York; secretary-treasurer, Dr. Sidney K. Simon, New Orleans, and assistant secretary, Dr. Allen J. Smith, Philadelphia.

Gynecologists to Meet.—The annual meeting of the American Gynecological Society will be held in Chicago, May 24 to 26, with headquarters at the Congress Hotel. Three morning sessions and one evening session will be held. The morning sessions of May 24 and 26 and the evening session of May 25 will be held in the Florentine Room of the Congress Hotel, and the morning session of May 25 will be held at the South Shore Country Club. Drs. Thomas W. Eden, London, and Charles Jacob, Brussels, Belgium, will be guests of the society and will read papers. Dr. Thomas J. Watkins is chairman of the committee of arrangements, and the profession of Chicago is cordially invited to be present.

Air Service Surgeons Meet.—At the annual meeting of the Air Service Medical Association of the United States held in New Orleans, April 27, the following officers were elected: president, Col. Albert E. Truby, M. C., U. S. Army, Washington, D. C.; vice presidents, Col. Robert A. Strong, M. R. C., U. S. Army, New Orleans, Col. Louis H. Bauer, M. C., U. S. Army, Mineola, N. Y., Col. J. O. McReynolds, M. R. C.,

Dallas, Texas, Col. Isaac W. Jones, M. R. C., U. S. Army, Los Angeles, and Major Samuel Mederith Strong, M. C., U. S. Army, Carlstrom Field, Fla., and secretary-treasurer, Col. Nelson Gapen, M. C., U. S. Army (retired), Washington, D. C.

Medical Veterans of World War Meet.—At the annual meeting of the Medical Veterans of the World War held in New Orleans, April 26, the following officers were elected: president, Dr. Frank Billings, Chicago; vice president, Admiral Edward R. Stitt, U. S. Navy; secretary-treasurer, Col. Frederick F. Russell, M. C., U. S. Army, Washington, D. C., and trustees, Drs. Hubert Work, Pueblo, Colo., John M. Dodson, Chicago, George E. Brewer, New York, Joel E. Goldthwait, Boston, James C. Perry, Washington, D. C., and Col. Frank R. Keefer, M. C., U. S. Army, Washington, D. C. The next annual meeting will take place in Boston on the day preceding the meeting of the scientific assembly of the American Medical Association.

FOREIGN

Training School Re-equipped.—Rudolfinerhaus, the oldest and best known training school for nurses in Vienna, founded by Professor Billroth, has been reequipped by the American Red Cross and arrangements have been made whereby nurses can go back to their prewar work.

Token of the Gratitude of France.—The *Journal officiel*, of Paris, published in its issue of Feb. 24, 1920, the names of two Americans to whom had been presented the Médaille de la reconnaissance française, Major Haynes and Major Albert J. Chesley, both connected with the American Red Cross.

Chateau Made Into Sanatorium.—The American Red Cross Commission to Belgium has completed the purchase of the estate of Baron de Naere at Aertrycke near Thourout. The chateau stands on one of the highest points in Flanders, has spacious grounds and will accommodate several hundred patients. Baron Van de Gracht has given 200,000 francs to aid in the equipment of a sanatorium.

Roentgen's Retirement.—At the close of the winter semester this spring Professor Roentgen retired from his chair (experimental physics) at the University of Munich and resigned likewise the charge of the Physikalisches Institut. His discovery of the rays that bear his name was made at Würzburg in 1895. Although not a physician, the profession can almost claim him on account of the way it has appropriated his discovery. He was born March 27, 1845.

Salaries of Public Health Officers.—At the suggestion of the Society of Medical Officers of Health and the British Medical Association, the medical journals of England have decided to reject all advertisements for assistant medical officers of health when the annual salary offered is less than £500, exclusive of traveling expenses. The agreement draws attention to the inadequate remuneration of physicians in the public service, for salaries in many cases have remained unchanged despite the increased cost of living.

Extension of Compulsory Health Insurance in Germany.—The *Deutsche medizinische Wochenschrift* for April 15 brings word that the committee appointed by the government has reported in favor of raising the income limit for compulsory insurance against sickness to 20,000 marks. By means of the new "simplified legislation" system, this became a law April 26. The editorial comment is to the effect that "even in an absolute monarchy, the law-making machine could not turn out anything worse than this new regulation in the so-called 'most democratic republic in the world.' In connection with the compulsory family health insurance and recent enactments in regard to the war disabled, nine-tenths of the total population are thus withdrawn from private medical practice."

Personal.—Prof. A. Calmette of Lille and Paris recently visited Athens to inaugurate there the Pasteur Institute of Greece. He was accompanied by Drs. Abt and Blanc who are to remain in charge of the new institution. Calmette's pioneer research and successful application of antivenins, antiplague serum, and the ophtho-tuberculin reaction are well known, and his antituberculosis dispensary at Lille was the mother preventorium. He was appointed to succeed Metchnikoff in the Pasteur Institute at Paris, but on account of the German occupation of Lille was able only recently to enter on his post as subdirector, under Roux.—The Constantinople Medical Society receives an appropriation from the state. At the recent election, the officers chosen were, for president, Dr. Trantas, for secretary, Dr. A. S. Papadopoulos, and for treasurer, Dr. Antonacopoulos.

Government Services

Medical Officers Honored by King

The king of England, on the recommendation of Sir Douglas Haig, made Nov. 7, 1917, has voiced his appreciation of the distinguished service in the field of the following officers of the Medical Corps, U. S. Army: Cols. Christopher C. Collins; George W. Crile, Cleveland; Harvey Cushing, Boston; Mathew A. Delaney; Robert U. Patterson; Harry L. Gilchrist; James D. Fife; Richard H. Harte, Philadelphia, and Lieut.-Col. Lucius L. Hopwood.—Miss Julia Stimson, superintendent of nurses, U. S. Army, has also received a like token of appreciation from the king.

Care of Speech and Hearing Defects

The Federal Board for Vocational Education estimates that there are among the injured veterans of the World War between ninety and 100 cases of men whose speech became absolutely unintelligible as the result of mouth or neck wounds, aphasia, or other causes. Of these men 25 per cent. are still in the hospital and 50 per cent. are in training or approved for training. The courses followed are agriculture, auto mechanics, commercial courses and chemistry. There are probably several thousand men throughout the country who became deaf in one ear, or who have suffered slight impairment of hearing in both ears. However, there are only about 200 for whom lip reading is necessary. Therefore, the approximate number of hearing and speech defect cases will be about 300.

Vocational Schools in Hospitals

A vocational school for veterans of the recent war may be established by the Federal Board for Vocational Education in any hospital where there are ex-service men in groups of sufficient numbers to justify the establishment of such a school. With this idea in mind, an officer of the Public Health Service made a survey which took in hospitals in the soldiers' homes at Dayton, Ohio, Marion, Ind., Danville, Ill., and Milwaukee; three Public Health Service hospitals—P. H. S. Hospital No. 30 and the Marine Hospital, both at Chicago, and P. H. S. Hospital, Markleton, Pa.; the private sanatorium at Catawba, Va., and the county hospital, "Healthwin," at South Bend, Ind.

Foreign Letters

BUENOS AIRES

April 3, 1920.

Lethargic Encephalitis

While this disease has been observed in Montevideo, no cases had been reported so far in Argentina. Recently, however, Dr. J. P. Navarro has reported a case (*Semana Médica* 9:283, 1920) and Dr. Gaspar Teglia three (*Revista Médica del Rosario* 10:1, 1920).

Typhus Fever

The epidemic of typhus fever has not yet crossed the Andes in spite of the severity it has assumed in Chile (12,068 cases with 3,560 deaths from October to December, 1919). But in the northern part of Argentina, small foci have persisted in some villages of the province of Salta, which are situated in the mountains and have very poor communications. Some new cases have also been observed recently in the district of San Carlos. The national department of public health has decided to remove to La Quiaca the sanitary station, previously installed at Humahuaca.

Plague

For the last few months there have been occurring cases of bubonic plague in practically all of the South American countries, especially in the southern part Brazil, Uruguay and Argentina. The spread of the disease has coincided with the removal of the stored wheat. The national department of public health has increased the number of sanitary commissions, having created another one at Cordova, presided over by Dr. Ricardo Argerich, with three subcommissions under Drs. Pasalacqua, Machado and Pedrazzini, respectively.

National Department of Public Health

Dr. Capurro, president of the national department of public health, has just been elected a member of the House of Representatives, Dr. Teófilo Lecour becoming for the time being acting president. It is to be regretted that this department should be considered a political institution, as this causes constant changes in its personnel.

The Control of "Patent Medicines"

The ministry of health has appointed a committee to consider and advise on the legislative and administrative measures to be taken for the control of the quality and authenticity of such therapeutic substances offered for sale as cannot be tested adequately by direct chemical means. The committee includes Dr. H. H. Dale, head of the department of biochemistry and pharmacology under the Medical Research Council, and Dr. C. J. Martin, director of the Lister Institute of Preventive Medicine. In 1912, a select committee of the House of Commons on "patent medicines" was appointed. In its report, issued in 1914, it thus summed up the legal position in regard to "patent medicines": "For all practical purposes, British law is powerless to prevent any

person from procuring any drug, or taking any mixture, whether potent or without any therapeutic activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses on the payment of a small stamp duty, for any price he can persuade a credulous public to pay."

The principal recommendations of the committee were: 1. That the administration of the law governing the advertisement and sale of "patent" and secret medicines be combined under one department of the state—the ministry of health when created, and then the Local Government Board. 2. That the manufacturers, proprietors and importers of such medicines be registered. 3. That an exact and complete analysis of every remedy, including medicated wines, with a full statement of the claims made for them, be furnished to the department. 4. That a special court or commission be constituted with power to permit or prohibit in the public interest, or on the ground of noncompliance with the law, the sale and advertisement of any remedy, and that the commission be a judicial authority, such as a metropolitan police magistrate sitting with two assessors, one appointed by the department and the other by some such body as the London chamber of commerce. 5. That the advertisement and sale (except the sale by a physician's order) of medicines purporting to cure the following diseases be prohibited: cancer, consumption, lupus, deafness, diabetes, paralysis, fits, epilepsy, locomotor ataxia, Bright's disease and rupture (without operation or appliance). 6. That all advertisements of remedies for venereal diseases and advertisements likely to suggest that a medicine is an abortifacient be prohibited. 7. That it be a breach of the law to use fictitious testimonials, or to promise to return money paid if a cure is not effected. Nothing was done to carry out these recommendations, for the war began and absorbed all the energies of the government. At last there is a prospect of checking the notorious nostrum evil.

Aeroplanes as Carriers of Disease Germs

In a lecture at the Royal Institution on "The Menace of Man's Dispersal of Insect Pests," Prof. H. Maxwell Lefroy pointed out how insect pests had been carried about the world from one country to another. This menace was going to be worse. In the first place, we were steadily linking up the world by railways, and especially by aeroplanes. Formerly we traveled by sea, and transported insects would die from the effects of a long journey; but the greatest carrier of pest-carrying insects was the aeroplane, which picked up insects, landed in a field, and deposited them, all within a few hours. The aeroplane was truly the disseminator of crop pests. During Dr. Chalmers Mitchell's flying trip through Africa, his aeroplane, while on the ground, had been attacked by white ants. The aeroplane could easily pick up the yellow fever breeding mosquito and bring it to another land within the space of a few hours. The tsetse fly, which engendered the African sleeping sickness, could be taken from West Africa to Brazil in a few hours. Among the insects the most to be dreaded was the chinch-bug, which in 1864 caused a loss of 73 million dollars' worth of wheat.

Proposed Medical Degree for a Bone Setter

Mr. Barker, the bone setter, has a large number of admirers among the public. A petition signed by more than 300 members of Parliament, past and present, has been presented to the Archbishop of Canterbury to exercise an ancient prerogative which empowers him to grant medical degrees in favor of Mr. Barker. The prerogative now, how-

ever, is in desuetude. It originated in the control once exercised by the church over the practice of medicine. Some years ago it was last exercised to confer the degree of M.D. on an already qualified physician, in consideration of some philanthropic or charitable work. As reported previously in *THE JOURNAL*, there was an agitation among members of Parliament to obtain for Mr. Barker an honorary degree from some of the universities in consideration of his services to wounded soldiers. It was unsuccessful, and it does not seem likely that the present attempt will have any better result.

Arsenic in Sugar; Sixty Persons Poisoned

An outbreak of arsenic poisoning, affecting sixty people, has occurred at the village of Haslemere, Surrey. About twenty households were involved, and among the victims were three bottle-fed babies. Suspicions of food poisoning were first aroused when three members of a family were seized with severe vomiting and internal pains after drinking some tea. When it was found that another member of the family, whose tea had not been sweetened, was unaffected, the sugar on the table was removed for examination, and the shop where it was purchased was visited by the local health officer. It was then discovered that a barrel of moist sugar recently arrived had become contaminated with a liquid preparation of some kind largely composed of arsenic. Inquiries led to the discovery that during transit by rail the sugar had come into contact with a leakage from a tin of weed killer, which contained arsenic. So far none of the cases have been fatal.

PARIS

April 15, 1920.

The Supply of Meat and Fish

Free commerce has been restored in the importation of frozen meats, until now a monopoly. A shortage is not to be apprehended, for the world supply of frozen meats has been found amply equal to consumption; in certain countries even, such as England, there is an overabundance. Moreover, there is no shortage of refrigerator ships in France since replenishment has proceeded almost entirely with French boats. Nevertheless, even though freedom of commerce is assured, the price remains under state control, which will prevent speculative attempts to increase the price exorbitantly. In spite of these precautions, consumption of frozen meats has really become less and less advantageous because of the depreciation of the franc. If this low standard continues, it will be necessary to employ the most logical meat substitute—fish. For this, it is necessary to assist the fishing industry, and above all, to help the work of steam trawlers whose yield is greater. The undersecretary of food control is at present engaged on this matter and particularly on a plan to obtain special concessions for coal trawlers. In anticipation of considerable traffic in fish, the railroad companies have also made some important preparations by setting up cold storage depots and by carrying refrigerator cars to preserve and transport the products of the fishing industry.

The Campaign Against Cancer

M. Le Troquer has just introduced a measure in the municipal council tending to assist the campaign against cancer, the ravages of which are increasing incessantly. Whereas in 1910 there were 3,073 cases of cancer, based on the number reported by physicians, in the following year there were 3,619. In the face of this state of affairs, M. Le Troquer thinks it opportune to encourage the use of radium in the treatment of cancer. Unfortunately, in Paris itself the *Assistance publique* is not in a position to give indigents the benefit of such special treatment, for no hospital has any

radium. M. Le Troquer likewise proposes the creation of a scientifically autonomous dispensary attached to the radium institute of the University of Paris, to which shall be entrusted 2.5 grams of radium to be purchased through an appropriation of 2,500,000 francs, which is requested in the measure.

Honor to Dr. Jacques Vaillant

The municipal council of Paris has unanimously expressed its deep regard for Dr. Jacques Vaillant, chief of the radiographic laboratory at the Hôpital Lariboisière, who recently suffered amputation of the left arm because of serious injuries from radiodermatitis.

Congress of Physiology

A congress of physiology will be held in Paris, July 16-20, under presidency of Dr. Charles Richet. Applications and assessments (35 francs) should be sent to M. Lucien Bull, treasurer, Institut Marcy, avenue Victor-Hugo, Boulogne-sur-Seine; correspondence should be addressed to Professor Gley, Collège de France, 14 rue Monsieur-le-Prince, Paris.

Decrease in the Birth Rate

The National Alliance for Increasing the Population of France recently published the figures of the fluctuation of the civil population of Prussia in comparison with those of France. From July 1, 1914, to June 30, 1918, exclusive of deaths in the armies, the population of uninvaded France (33,000,000 inhabitants) decreased 973,000; that of Prussia (42,000,000 inhabitants) decreased 313,000 during the same period. With a civil population of 9,000,000 less than Prussia, France suffered a loss three times as great. Taking into consideration the ten invaded departments, for which complete statistics are lacking, but where the birth rate has been very low and the mortality quite high, the decrease in the population of France appears even much more formidable. The great difference between France and Prussia is due entirely to the higher German birth rate, which, although it decreased during the war in the same proportion as that of France, is still much higher than in the latter country.

Physical Exercise in the Army

By an order of M. André Lefèvre, minister of war, sports have been made compulsory in the army. Hereafter all field officers and captains must be qualified to direct the physical exercises of their commands, and all lieutenants and sublieutenants must be able to perform the functions of captain of a football team.

Promotion of Clinical Research

A committee has just been formed under the patronage of M. Paul Deschanel, president of the French republic, and with M. Raymond Poincaré, ex-president of the republic as honorary president, with a view of establishing at Paris a great laboratory of chemical research, under the name of *Institut de la Victoire*. Dr. Emile Roux, director of the Pasteur Institute, Prof. Charles Richet of the Faculty of Medicine, and Professor Bordas of the Collège de France, are among the members of the organization committee.

Committee on Mental Hygiene

The minister of hygiene, assistance and social providence has just instituted a committee on mental hygiene, with instructions to make a technical study of all questions relating to mental hygiene, psychiatry, and applied psychophysiology of the various social activities.

Death of Dr. G. Sarda

Announcement has been made of the death of Dr. G. Sarda, aged 65, professor of medical jurisprudence at the University of Montpellier.

Deaths

John Chalmers DaCosta, Jr. ☉ M. C., U. S. N. R. F., Philadelphia; Jefferson Medical College, 1893; aged 48; died in St. Timothy's Hospital, April 26, from skull fracture sustained in an automobile accident. He was lieutenant and assistant surgeon, U. S. V., during the Spanish-American War; was well known as a specialist on internal medicine, holding the position of associate professor of medicine in his alma mater; attending physician at Jefferson Hospital, consulting physician to the Northwestern General Hospital and hematologist to the German Hospital. He was a fellow of the American Academy of Medicine, and of the College of Physicians of Philadelphia, and the author of articles and monographs on clinical hematology, surgical hematology and the principles and practice of diagnosis.

John Williams Severin Gouley, Brooklyn; College of Physicians in the City of New York, 1853; University of the City of New York, 1878; aged 87; died at the home of his daughter, April 26, from senile debility. He was visiting surgeon to Bellevue Hospital from 1859 to 1898; consulting surgeon to Bellevue and St. Vincent's hospitals, New York City, and at one time professor of anatomy in the Vermont College, Woodstock, and demonstrator of anatomy in the University of the City of New York. During the Civil War he was attached to the medical staff of the Central Park Military Hospital, and later served with the armies in the field.

Adolph August Hoehling, Medical Director, Rear Admiral, U. S. Navy (retired), Chevy Chase, Md.; University of Pennsylvania, Philadelphia, 1860; aged 81; died, April 25, from arteriosclerosis. He entered the Navy as assistant surgeon, April 4, 1861, was promoted to passed assistant surgeon in 1865, to surgeon in 1867, to medical inspector in 1885, to medical director in 1893, and to rear admiral on June 29, 1906, the date on which he was retired for disability incident to the service, after thirteen years and five months' sea service.

Louis Nott Lanehart ☉ Hempstead, L. I., N. Y.; Albany (N. Y.) Medical College, 1883; aged 50; one of the organizers of, and surgeon to, the Nassau Hospital; surgeon to the Babylon, Mercy, and Eastern Long Island hospitals, and consulting surgeon to the Williamsburg Hospital; health officer of Hempstead village and township; died, April 25, from heart disease, after an operation on his throat.

Lunsford Eliga Cox, Greenwood, Ind.; State College of Physicians and Surgeons, Indianapolis, 1907; aged 37; a member of the Indiana State Medical Association; once coroner of Johnson County; who had been under treatment in a sanatorium for nervous diseases in Indianapolis, is said to have committed suicide at that institution, by strangulation, April 26.

John Mitchell Benedict, Woodbury, Conn.; University of the City of New York, 1882; aged 68; a member of the Connecticut Medical Society; visiting physician and surgeon to the Waterbury Hospital; major and surgeon of the Second Infantry, Connecticut National Guard from 1889 to 1895; died, April 23, from angina pectoris.

John Gailey Campbell ☉ Chicago; Northwestern University Medical School, Chicago, 1896; aged 50; instructor in pediatrics and formerly instructor in physical diagnosis and clinical medicine in his alma mater; medical referee of the Mutual Life Insurance Company of New York; died, May 10, from pneumonia.

David Andrew Conrad ☉ Santa Barbara, Calif.; University of California, Berkeley and San Francisco, 1893; aged 48; captain, M. C., U. S. Army (emergency); who had been under treatment at the Letterman General Hospital, Presidio of San Francisco; died in Santa Barbara, April 6.

Claren Emmett Pfeifer ☉ Columbus, Ohio; Ohio Medical University, Columbus, 1904; aged 45; captain, M. R. C., U. S. Army, and discharged April 25, 1918; head of the United States Public Health Service for the central district of Ohio; died in his office, April 23, from diabetes.

Joseph Fraenkel, New York City; University of Vienna, Austria, 1890; aged 52; assistant professor of clinical medicine in Cornell University Medical School, New York City; a fellow of the New York Academy of Medicine; died, April 24, from disease of the stomach.

Ewing Jordan, Philadelphia; University of Pennsylvania, Philadelphia, 1871; aged 73; from 1880 to 1885 first assistant physician to the Pennsylvania State Hospital, Norristown; died at the home of his brother in Philadelphia, April 28.

Julius Scheider, New York City; University of Vienna, Austria, 1872; aged 74; a member of the staff of the German Hospital, New York City, in the department of diseases of children; died, April 26, from heart disease.

Donald Meronan Kelley, Brookston, Ind.; University of Michigan, Ann Arbor, 1881; aged 65; one of the founders and president for several years of the Brookston Canning Company; died, April 16, from arteriosclerosis.

Richard James Plumer Goodwin, Malden, Mass.; Harvard University Medical School, 1865; aged 82; a member of the Massachusetts Medical Society; surgeon of U. S. Volunteers throughout the Civil War; died, April 19.

Arthur Judson Benedict ♂ Newburgh, N. Y.; University of Buffalo, N. Y., 1876; a specialist in diseases of the ear, nose and throat; died in St. Luke's Hospital, Newburgh, April 17, after an operation for gallstones.

Willis Curtis Cook, Brockport, N. Y.; Toledo (Ohio) Medical College, 1887; aged 88; for forty-two years a practitioner of medicine; died at the home of his granddaughter in Albion, N. Y., April 14.

Arthur Emery Green ♂ Lansing, Mich.; University of Michigan, Ann Arbor, 1902; aged 44; a specialist in pediatrics; until 1919 a practitioner of Leslie, Mich.; died, April 17, from heart disease.

William Dawson Robinson, East Orange, N. J.; Bellevue Hospital Medical College, 1879; aged 77; a member of the Medical Society of New Jersey; a veteran of the Civil War; died, April 13.

John William Clarke ♂ Lyndhurst, N. J.; Medico-Chirurgical College of Philadelphia, 1901; aged 52; health officer of Lyndhurst for several years; died, April 12, from cardio-renal disease.

Mary Parker, Waltham, Mass.; Hahnemann Medical College, Chicago, 1910; aged 47; a member of the staff of the Massachusetts Homeopathic Hospital; died, April 8, from carcinoma.

Charles James Helm ♂ Peru, Ind.; Harvard University Medical School, 1887; aged 57; consulting surgeon at the Wabash Railway Hospital, Peru; died, April 27, from pneumonia.

Wallace Harlow Deane, Springfield, Mass.; Yale University, New Haven, Conn., 1877; aged 66; a member of the Massachusetts Medical Society; died, April 10, from pneumonia.

Valcollon Warsaw Mather, Kansas City, Mo.; Pulte Medical College, Cincinnati, 1883; aged 73; died in the Robinson Sanitarium, Kansas City, April 18, from cerebral hemorrhage.

Reginald Francis Cox, Alexandria, Va.; Tulane University, New Orleans, 1918; aged 29; died at the home of his parents in Alexandria, April 19, from tuberculosis following influenza.

Henry Tupper Drane, Clarksville, Tenn.; Bellevue Hospital Medical College, 1873; aged 70; died at the home of his daughter in Brookhaven, Miss., March 24, from pneumonia.

William R. Todd, Seattle; Rush Medical College, 1879; aged 90; at one time county physician of Eureka County, Nev., and of Clear Creek County, Colo.; died, April 23.

Christian P. Glahn, Palmyra, Mo.; Washington University, St. Louis, 1902; aged 45; health officer of Marion County; died, April 28, from lethargic encephalitis.

Louis Charles Sinclair, Ripley, Ont.; University of Toronto, Ont., 1896; died in the Kincardine (Ont.) General Hospital, March 7, from pneumonia.

Julius A. Goltz ♂ Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1887; aged 67; died, April 1, from cirrhosis of the liver.

Cyprian R. Wright, Frankton, Ind.; Medical College of Indiana, Indianapolis, 1888; aged 57; died, April 17, from carcinoma of the prostate.

Eldridge Allen Toby, River Falls, Wis.; University of Vermont, Burlington, 1874; aged 72; died, April 23, from cerebral hemorrhage.

Correction.—The notice of the death of Dr. Julius Jerome Goldstein which appeared in THE JOURNAL of May 1, is an error.

Marriages

ERASMUS DARWIN FENNER to Mrs. Sadie Cameron McDonald, both of New Orleans, April 28.

JESSE HENRY ROTH, Kankakee, Ill., to Miss Josephine McAuley of Chicago, recently.

RALPH TOWNSEND TRAVERS to Miss Catherine Dayin, both of New York City, May 1.

CYRIL M. SMITH to Miss Ednah Katherine Kolkebeck, both of Brooklyn, Dec. 20, 1919.

GRANT GOULD SPEER to Miss Eunice Amanda Parker, both of Los Angeles, April 28.

WILLIAM W. ALDERDYCE to Mrs. Litta Marie Crouse, both of Toledo, April 20.

WILLIAM SIMON CROWLEY to Miss Ethel Roth, both of Chicago, April 28.

Correspondence

TEACHERS IN THE PRECLINICAL SCIENCES

To the Editor:—For several weeks, nearly every number of THE JOURNAL has contained one or more statements by eminent professors in clinical departments in various medical schools, most of them delivered at the recent conference on medical education, damning the preclinical instructors. They state with absolute positiveness that the clinical departments should contain each its own pathologist, its own assistant skilled in physiologic technic, and others in other fields. Any dependence on the preclinical departments is thus to be rendered unnecessary, and the laboratory branches are to be left with even less clinical and hospital connection than at present. This aim appears to be everywhere a part of the plan for full-time clinical departments.

Soon after these addresses, the report of the committee of the National Research Council was published, revealing the really appalling conditions in the preclinical departments—the inferior pay and the lack of young men going into the medical sciences.

Now comes the report of the Council on Medical Education, Dr. A. D. Bevan, chairman, which indicts the preclinical instructors for being “ultrascientific,” and states bluntly that only men with the M.D. degree should be allowed in the preclinical chairs, and these instructors must be “able to give students the medical point of view,” and should be required “to keep in touch with the art and science of medicine.”

Nor is this all. Three of the leading medical schools in the East have vacant chairs of physiology, and it is commonly reported that men fit to fill them are lacking in America, and that the importation of foreigners for one or more of them is under consideration. Such a rumor, even assuming it untrue, is a humiliation and discouragement to American physiologists and to American science in general. It indicates that something is fundamentally wrong.

The situation is: No man of the Ph.D. variety should be allowed in the preclinical chairs. No man of ability with the M.D. degree will in fact strive for them or stay in them, against the immensely greater opportunities and advantages offered now, and to be offered in even richer measures in the future, by the clinical departments. Unless something pretty radical is done and done soon, either these chairs will be filled by men with the Ph.D., or they will be vacant.

Perhaps the instruction in the medical sciences will then be given by the pathologic, physiologic, pharmacologic and other assistants, expert in each branch, who are to be included in the clinical departments. Until the freezing of the source brings about its inevitable result, this solution would have one great advantage to recommend it. It would attract, instead of repelling. Under it the young men giving

this instruction would have before them an open road to a future worth a man's efforts, namely, to become professors of medicine and surgery.

One committee, looking at matters from a standpoint opposite to that of the Council on Medical Education, has even advocated encouraging the development of preclinical instructors of the Ph.D. variety. But to get young men into the medical science through the avenue of the Ph.D. is, under present conditions, a cruel proposition. They get in; they cannot get out, as an M.D. could; and there is then nothing for them to do but to accept the starvation wages, perhaps a half of the pay of men no abler nor more loyal and industrious in the clinical chairs, plus such oburgation for their "lack of a medical standpoint" as the columns of *THE JOURNAL* have lately carried.

I am one of the men who, in spite of the handicap of the Ph.D., have devoted their lives to making what contribution they could to medicine. And I ask: How do Dr. Bevan and the others expect us to get or keep a medical standpoint? What opportunity have we? Suppose a man receives a call to the chair of medicine, and he asks "What will be my relation to the hospital?" The answer is, "Chief of everything in your field, with power and subordinates and money." Suppose, on the contrary, that a man is called to the chair of physiology, and asks the same question; the answer will be, "Nothing whatever." And as like as not there will be added, *sotto voce*, "We don't want you around the hospital; any applications of physiology to diagnosis, treatment or clinical research we will supply in our clinical departments." This is particularly true of the full-time clinical departments, as planned, according to every description thus far published. What would the surgeons say if the department of medicine put in a surgical assistant? Or how would the professor of medicine like to have the department of surgery include an internist in its staff? Yet each of these departments in many places insists on having its own pathologic laboratory with technicians and instructors.

Do not misunderstand. Not a word is here said against the "full-time plan." But if the difference in the status of the clinical and the preclinical instructors is made as glaring as is proposed, there is no question which field of life work the young man of ability will choose, and which he will reject.

We are stigmatized as "off horses," and yet we are not allowed in the team. Doubtless there will be exclamations over this: What can a physiologist do around a hospital? The answer is that he can have charge of the things which physiology has contributed: electrocardiography and sphygmography, basal metabolism, electrodiagnosis, blood analysis, respiratory analyses and tests, etc. The present inadequacy of clinical work regarding the hematorespiratory functions is simply monstrous.

The thing which, even more than low pay, is inhibiting the manufacture of physiologists is the lack of a market in which the product can be sold. To do business on any scale there must be some rapidity of turn over. At present an assistant starts in a physiologic laboratory, and after fifteen or twenty years he may become a professor. Think of a business with a turn over once in fifteen or twenty years! It is more like a cemetery than a career. Pathology and biochemistry have larger markets, in technical positions to be filled outside of schools, than physiology and anatomy; and they are doing correspondingly more business and are more alive.

But suppose that all this were changed, and that the doors of opportunity were open! The regular course of events for every young man fitting himself for the highest grade of clinical work would then begin (after a year in the hospital) with a couple of years spent entirely in a laboratory. He

would then be promoted to one of the clinical physiologic instructorships, or some other liaison position, for example, in charge of the electrocardiograph. There, while still part of a laboratory department, he would come into contact with clinical phenomena and apply his laboratory training. He would become more and more interested in clinical medicine and would in a few years pass on into one of the clinical departments, leaving a place for the promotion of another man from the laboratory. There could then be a turn over every two or three years. One man in fifteen or twenty would finally become a professor of some preclinical branch. (There are only a dozen or two good positions of this sort to be filled in each generation in a nation of one hundred million people.) There would then be a group from whom

The difficulty about such liaison arrangements as those here clinical medicine, would be none the worse for their early contact with science beyond the student stage.

It would be a part of this plan also to cut down the required preclinical courses, and to enlarge the electives in junior and senior years in the various branches of clinical physiology and like subjects.

The difficulty about such liaison arrangements as those here suggested is that they involve a system of functional organization and cooperation, instead of the system of water tight compartments which now prevails, and which practically every one who has discussed medical education lately seems to assume as a matter of course. They seem unaware of the fact that some of the largest and most ably managed industries in the country have discarded the water tight compartment system, and operate today under what is termed "functional organization." This is true, for example, of all the companies of the Bell Telephone System. There is urgent need that the authorities and donors who today are directing the development of medical education should inform themselves regarding that system, of which the fundamental principle is a real cooperation.

There are many physiologists in America who can say truly that the thing for which we have striven hardest and against the greatest inertia for many years has been the development of our lines of work into the clinical field. As chairman of the Section on Pathology and Physiology of the American Medical Association in 1911, I made the topic of my address "Clinical Physiology—An Opportunity and a Duty." The gentlemen who now attack us might advantageously look this paper up in the files of *THE JOURNAL* and reread, or at least, read it. It can be asserted without fear of successful contradiction, I believe, that in general the professors of physiology in America fulfil the duty described in that paper to the limit of their opportunities. It is the opportunity that is lacking.

YANDELL HENDERSON, PH.D., New Haven, Conn.
Professor of Physiology, Yale University
School of Medicine.

"BONDS NOT NECESSARY FOR PHYSICIANS"

To the Editor:—My attention has just been directed to your editorial comment under the caption "Bonds Not Necessary for Physicians" (*THE JOURNAL*, April 10, 1920, p. 1029).

I am sure that it was not your intention to direct your criticism against the legal profession as a whole, but your article does to a marked degree refer and reflect on all of the legal profession.

With reference to the specific matter at issue, I wish to state that I not only procured a supply of these blanks, but filled them out and took the acknowledgments in my office and made no charge of any kind or character, and there has never to my knowledge been any charge made in my office to members of the medical profession, for services of this

character. And I know this to be the general rule in our profession.

I was shown one of the circulars to which you refer, and I immediately took the matter up with the Bar Association of St. Louis, who promptly investigated the matter with the result that it was found that the party who had sent out the circulars in question was not a member of the Bar and was not licensed to practice law.

With these facts before you, I feel certain that you will wish to modify your article of April 10, which is a direct reflection on the legal profession as a whole.

S. C. BATES, Springfield, Mo.

Attorney and Counselor at Law.

[COMMENT.—Our comment did not reflect on the legal profession. The criticism was not on the fact that a charge was made for services. The circulars criticized conveyed the impression that a bond was necessary for physicians in order to secure a permit, and that the charge made was for the bond and not for the services. In any event, if physicians need legal assistance it would seem much better to utilize home talent.—Ed.]

RAILROADS AS A SOURCE OF INFECTION

To the Editor:—In speaking of the spread of tropical diseases in the United States (THE JOURNAL, Feb. 14, 1920, p. 463), you do not mention what must be a prolific source of spread of any intestinal infections: the absolute lack of control of intestinal discharges of passengers on trains and boats. These discharges are daily scattered along all the routes of travel. Is it not time that some means were sought for a more sanitary way of disposing of them? I have no suggestions to offer, except that the separation of the urine and feces might make it more feasible to destroy the latter instead of sending them forth as a menace to the public health. Surely the Public Health Service, which has done so much in the way of public hygiene, could devise proper means for combating this evil.

R. W. DUNLAP, M.D., Chefoo, China.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THYROID EXTRACT IN REDUCTION OF WEIGHT

To the Editor:—I have had an inquiry in regard to the use of thyroid extract for persons greatly overweight. I wish you would make some observation in regard to this in Queries and Minor Notes.

J. D. GRAHAM, M.D., Columbus, Kan.

ANSWER:—When given in full dosage for long periods of time, thyroid extract produces anemia, emaciation and muscular weakness, excessive sweating, increased heart rate, etc. It will probably cause loss of weight, and with it faintness, loss of strength and debility. Thyroid extract has been used in some "fat reducers." It is far too dangerous a drug to be self-prescribed. If used at all for the reduction of weight, the patient should be under competent medical observation.

Training for Medical Research.—To qualify a man to be a skilled investigator in bacteriology, in physiology, and in chemistry, many years of special training are necessary. If it be realized that before a man is qualified to undertake an investigation for the prevention and cure of disease—the real object of medical research—he must have a knowledge of symptoms, it will be seen that a training is required which is bound to take a great many years.—J. MacKenzie, *Brit. M. J.* 1:109 (Jan. 24) 1920.

COMING EXAMINATIONS

- CALIFORNIA: San Francisco, June 28-July 1. Sec., Dr. Chas. B. Pinkham, 135 Stockton St., San Francisco.
DELAWARE: Wilmington, June 15-17. Pres. Medical Council, Dr. H. W. Briggs, 1026 Jackson St., Wilmington.
FLORIDA: Eclectic Board, Jacksonville, June 18-19. Sec., Dr. G. A. Munch, 1306 Franklin St., Tampa.
FLORIDA: Regular Board, Jacksonville, June 14-15. Sec., Dr. Wm. M. Rowlett, Citizens Bank Bldg., Tampa.
GEORGIA: Atlanta, June 9-11. Sec., Dr. C. T. Nolan, Marietta.
ILLINOIS: Chicago, June 14-17. Director, Mr. Francis W. Shepardson, Springfield.
IOWA: Iowa City, June 16-18. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.
KANSAS: Topeka, June 15-16. Sec., Dr. H. A. Dykes, Lebanon.
KENTUCKY: Louisville, May 17. Sec., Dr. A. T. McCormack, 532 W. Main St., Louisville.
LOUISIANA: New Orleans, June 10-12. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.
MARYLAND: Baltimore, June 15. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.
MICHIGAN: Ann Arbor, June 8-10. Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit.
MINNESOTA: Minneapolis, June 1-4. Sec., Dr. Thos. McDavitt, 539 Lowry Bldg., St. Paul.
MISSOURI: St. Louis, June 14-16. Sec., Dr. Geo. H. Jones, State House, Jefferson City.
NATIONAL BOARD OF MEDICAL EXAMINERS: Philadelphia, May 19-26. Sec., Dr. J. S. Rodman, 1310 Medical Arts Bldg., Philadelphia.
NEBRASKA: Lincoln, June 9-11. Sec., Department of Public Welfare, Mr. H. H. Antles, Lincoln.
NEW JERSEY: Trenton, June 15-16. Sec., Dr. Alexander MacAlister, State House, Trenton.
NEW YORK: New York, Albany, Syracuse, Buffalo, May 18-21. Assistant, professional examinations, Mr. Herbert J. Hamilton, Education Bldg., Albany.
NORTH CAROLINA: Raleigh, June 21. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.
OHIO: Columbus, June 8-11. Sec., Dr. H. M. Platter, State House, Columbus.
RHODE ISLAND: Providence, July 1-2. Sec., Dr. Byron U. Richards, State House, Providence.
SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Booser, 1806 Hampton St., Columbia.
TENNESSEE: Memphis, Nashville and Knoxville, June 11-12. Sec., Dr. A. B. DeLoach, 1001 Exchange Bldg., Memphis.
TEXAS: Galveston, June 22-24. Sec., Dr. Thos. J. Crowe, Trust Bldg., Dallas.
VERMONT: Burlington, June 29-July 1. Sec., Dr. W. Scott Nay, Underhill.
VIRGINIA: Richmond, June 22-25. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.
WISCONSIN: Milwaukee, June 29-July 1. Sec., Dr. John M. Dodd, 220 E. Second St., Ashland.
WYOMING: Cheyenne, June 7-9. Sec., Dr. J. D. Shingle, Cheyenne.

Wyoming February Examination

Dr. J. D. Shingle, secretary of the Wyoming State Board of Medical Examiners, reports the written examination held at Thermopolis, Feb. 2-4, 1920. The examination covered 10 subjects and included 100 questions. An average of 75 per cent. was required to pass. Two candidates were examined, who passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1918)		87.5
St. Louis University	(1906)		75

South Dakota January Examination

Dr. Park B. Jenkins, secretary of the South Dakota State Board of Health, reports the written examination held at Pierre, Jan. 13-15, 1920. The examination covered 13 subjects and included 105 questions. An average of 75 per cent. was required to pass. Of the 23 candidates examined, 22 passed and 1 failed. Five candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Chicago College of Medicine and Surgery	(1918)		83.2
College of Physicians and Surgeons, Chicago	(1908)		89.2
Northwestern University	(1916)		84.7
Rush Medical College	(1889) 85, (1916) 87.6, (1919)		88.9
Indiana University	(1908)		89.9
Sioux City College of Medicine	(1906)		79.8
State Univ. of Iowa Coll. of Med.	(1897) 78.1, (1904)		81
University of Louisville	(1909)		88
Harvard University	(1896)		84.6

Tufts College Medical School	(1915)	78.4
University of Michigan Medical School	(1919)	87.5
Nat'l Univ. of Arts and Sciences	(1915) 82,	78.2
Washington University	(1919)	81.4
John A. Creighton Medical College	(1911)	84.6
University of Nebraska	(1918)	86.8
University College of Medicine, Richmond	(1907)	81.9
Marquette University	(1913)	83.3
Montreal School of Medicine and Surgery	(1903)	85.2

District of Columbia January Examination

Dr. Edgar P. Copeland, secretary of the District of Columbia Board of Medical Examiners, reports the oral and written examination held at Washington, Jan. 13, 1920. The examination covered 16 subjects and included 80 questions. An average of 75 per cent. was required to pass. Eight candidates were examined, all of whom passed. Two candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Arkansas		(1917)	75.5, 75.3
Georgetown University		(1918) 81.6,	(1919) 81.8, 86.8

Book Notices

TEXT-BOOK OF MEAT HYGIENE WITH SPECIAL CONSIDERATION OF ANTEMORTEM AND POSTMORTEM INSPECTION OF FOOD-PRODUCING ANIMALS. By Richard Edelmann, Ph.D., Medical Counsellor. Fourth edition by John R. Mohler, A.M., V.M.D., Chief, United States Bureau of Animal Industry. Cloth. Price \$4.75. Pp. 472 with 166 illustrations. Philadelphia: Lea & Febiger, 1919.

When we consider that meat and meat products constitute a large part of the diet of the American people, physicians in this country cannot very well escape the obligation of possessing at least a general knowledge of the subject of meat inspection and meat hygiene in general, just as a modern pediatrician is of necessity interested in and must inform himself on the developments of milk hygiene. It will hardly do to shift all the responsibility in these matters to the shoulders of the veterinary inspectors. There is still some meat and game on the market that is not inspected; and even as regards that which is inspected, with the immense mass of material passing through the hands of the inspectors, it can scarcely be expected that no diseased carcasses and no faulty meat products will be overlooked. Some knowledge of the problems with which meat inspectors have to deal, and more especially of the abnormal conditions and

diseases found in food-producing animals, will facilitate the diagnosis of pathologic conditions that arise from the consumption of meat or meat products which were not quite up to standard, but which escaped the watchful eye of the inspector or which deteriorated in quality in the interval that elapsed between the time when the stamp "U. S. Inspected and Passed" was affixed and the date of consumption. The book contains fifteen chapters, of which Chapters VII-XI will prove most interesting, as they cover such topics as the abnormal conditions and diseases of food-producing animals, postmortem changes of meat, the examination of preserved meats, chickens, game, fish, amphibia and crustaceans, and meat poisonings. As many diseases of the human body find their counterpart in animals, a comparative study of this sort will prove helpful; and for that purpose, the present work will furnish valuable aid.

THE NOSE, PARANASAL SINUSES, NASOLACRIMAL PASSAGEWAYS AND OLFACTORY ORGAN IN MAN. A Genetic, Developmental and Anatomico-Physiological Consideration. By J. Parsons Schaeffer, A.M., M.D., Ph.D., Professor of Anatomy of the Jefferson Medical College of Philadelphia. Cloth. Price, \$10 net. Pp. 370, with 204 illustrations. Philadelphia: P. Blakiston's Son & Co., 1920.

This study of the embryology, development and anatomy of the human nose, accessory sinuses, olfactory organ, and related structures bears evidence of exhaustive observation and research. Special consideration is given throughout to the important matter of anatomic variations or so-called anomalies. The author first describes the general embryology and development of the special organs under consideration, and carries this through fetal life, infancy and childhood, adding numerous photographs and drawings of specimens and dissections throughout these various stages. In this chapter is also a consideration of congenital defects. The following chapter is devoted to the anatomy of the fully developed nose, wherein the structures are treated as a whole and in correlated groups and in individual detail with excellent illustrations, all combining to convey an illuminating knowledge of the anatomy of the nose itself. Each of the next four chapters is devoted to one of the nasal sinuses, namely, maxillary, frontal, sphenoidal and ethmoidal. Each sinus is described in the fetal, childhood and adult stage, with special consideration of anatomic variations as regards size, shape, location, septums, diverticula, duplication, etc. Mention is made regarding the relation of the sphenoidal sinus to the hypophysis cerebri, optic nerve and commissure, cavernous sinus, and its contained structures. A consideration of the nasolacrimal apparatus is followed by a description of the nasal mucosa with its histologic variations as to location, etc. There is then a chapter devoted to the blood and lymph-vascular systems, and another to the common sensory and sympathetic nerves. The next chapter describes the olfactory apparatus both as to its peripheral organ and central organ or olfactory brain. The final chapter treats of the physiologic functions of the nose. The volume is well written, and the illustrations are excellent.

ON FACIAL NEURALGIA AND ITS TREATMENT, WITH SPECIAL REFERENCE TO THE SURGERY OF THE FIFTH NERVE AND THE GASSERIAN GANGLION. By J. Hutchinson, F.R.C.S., Surgeon to the London Hospital. Cloth. Price, \$4. Pp. 216, with illustrations. New York: William Wood & Co., 1919.

This book contains a practical discussion of the symptoms and diagnosis of tic douloureux, as well as of minor forms of neuralgic pains in the face due to demonstrable causes, such as carious teeth, ocular and nasal affections, and syphilis. The surgical anatomy is adequately presented and well illustrated; less must be said of the surgical treatment, which is not brought up to date. In particular, too little consideration is given to the greatly improved methods in gasserian ganglion and sensory root operations, perfected by American surgeons in the last fifteen years, while antiquated British methods are given preference. Considerable space is devoted to alcohol injections, especially to the work of the British imitators, while that of the French originators of the external method is scarcely considered. In spite of these shortcomings, however, this is a readable book, and will be found helpful by those especially interested in the subject.

Medicolegal

Workman's Compensation Before and After Amputation

(*Addison v. W. E. Wood Co. et al. (Mich.), 174 N. W. R. 149*)

The Supreme Court of Michigan says that the plaintiff suffered an accidental injury while in the employ of the W. E. Wood Company, and was paid compensation for total incapacity at the rate of \$10 a week for fifty-four and one-third weeks. His foot was then amputated, and payments at the rate of \$10 a week were continued until he had been paid and tendered compensation for 125 weeks, the compensation specified in the workmen's compensation law of Michigan for loss of a foot. It was contended for the defendants that the one injury which the plaintiff sustained resulted in the loss of a foot, entitling him to 125 weeks' compensation for such loss, to be computed from the date of the injury, the exact time when the foot was amputated having no material significance. But the industrial accident board awarded him compensation for total incapacity during the fifty-four and one-third weeks he was disabled without loss of any member, and after the operation continued compensation during 125 weeks more for loss of a foot; and the court affirms the award, concluding that the construction of law by the board as applied to the facts in this case was permissible within the wording, spirit and inferable intent of the law considered in all its provisions. It is within the spirit of the law, and does no violence to the wording of the sections considered, to construe them as authorizing compensation for existing total incapacity resulting from any injury to a member while medical skill is attempting to restore and save it, and until such time as developments have proved amputation necessary, followed by compensation for the loss of such member during the period fixed by the law after such loss becomes an actuality cognizable under the schedule.

Ratification of Employment of Physician

(*Baker v. Brown & Hockney, Inc. (Ark.), 215 S. W. R. 578*)

The Supreme Court of Arkansas says that the plaintiff, a practicing physician, sued the defendant, a lumber corporation, for \$1,110 on account of medical services alleged to have been rendered at the instance of the defendant to one of its employees. The defendant denied that it employed the plaintiff to render medical aid to the employee. It appeared in evidence that the general manager of the defendant's business at the place where the employee that was injured worked was especially authorized by the defendant to employ first aid medical assistance in case of injury to the employees, received while performing their duties. He employed the plaintiff to render medical aid to the employee, who had received a serious injury while engaged in the line of his duty. No limitation or restriction was placed on the plaintiff as to the extent of the employment. The general manager testified: "I told him we wanted him taken the best care of." Immediately after the injury, the general manager wrote a letter to the defendant, informing it of the injury, and possibly his employment of the plaintiff to treat the employee. Shortly thereafter the general manager went to the city where the corporation had its general office, and informed an officer and manager of the corporation that, according to the plaintiff, the employee was in pretty bad shape. The plaintiff continued to render medical services to the employee, except for a short time on account of illness, from January 30 to July 22, making a total of 185 visits. A short time prior to June 19, the plaintiff presented a partial account for services to the defendant, which carried a liability policy on its employees, and, on receipt of the plaintiff's bill for \$936, being a partial bill, sent it to an agent of the insurance company, and without replying to the plaintiff. The insurance company declined to pay plaintiff the bill on the ground that, under the terms of the policy, it was not responsible for first aid assistance or medical attention of physicians. When the evidence was concluded, the trial judge instructed the jury that the defendant was liable only for first aid services, in keeping with which instruction the

jury was directed to return a verdict for the plaintiff for \$24. In reversing the judgment rendered for that amount, and remanding the cause for a new trial, the supreme court says that the plaintiff conceded that the evidence was not sufficient to show general authority in the local general manager to employ physicians generally, but contended that there was sufficient evidence to present the issue of ratification by the defendant of the act of its agent in employing the plaintiff to treat the employee. It is a well-established rule that an employer may ratify the unauthorized acts of his agent by silence and acquiescence. There was no serious denial that the local general manager was the defendant's agent in the management of the lumber business at the place where the accident occurred. It might be, under the evidence recited above, that he exceeded his authority in the employment of the plaintiff to render medical assistance to the injured employee beyond first aid; but the evidence strongly tended to show that the defendant was apprised of the fact and remained silent. Under this state of case, the question of ratification should have been submitted to the jury. It was error to instruct the jury peremptorily to render a verdict for first aid only.

Infection Carried from Toe to Face

(*Bethlehem Shipbuilding Corporation, Limited, v. Industrial Accident Commission et al. (Calif.), 185 Pac. R. 179*)

The Supreme Court of California, in affirming an award under the workmen's compensation act for the death of one Caffrey, says that on Friday, July 26, 1918, he sustained a contused wound of the great toe of his right foot. He continued at his work Saturday, and also the following Monday. On Monday he had the toe dressed at an emergency hospital. Tuesday, the foot was so painful that after starting to work he returned home and undertook to treat the toe himself. August 1, he complained of a swelling of the face. On the following day, the symptoms of the face became alarming, and he was removed to a hospital, where it was discovered that there was a streptococcic infection of the injured toe. The skin surrounding the toe was in an erysipelatous condition, and there was a development of erysipelas on the face. The facial infection resulted in septicemia, from which he died, August 8. The industrial accident commission found that the germs which caused the facial infection were carried from the toe to the face by external means, and that Caffrey's death was proximately caused by the original injury. The medical testimony on which the commission based its finding that the germs which caused the facial infection were carried from the toe to the face by external means was, in effect, that such a method of transfer was exceedingly common, the transmission of the germs being very readily accomplished; that there was no reason to suppose that the infection had come from another source than the toe, and that, while it was within the realm of possibility for the infection to have come from another source, such a hypothesis was so very much the least probable that it seemed useless to theorize as to such a possibility in the face of facts indicating that the germs certainly must have been carried from the foot. The testimony showed that the experts were not indulging in mere conjecture or speculation. They were given what, on the facts before them, and in the light of medical science, appeared to be the most probable explanation of the event.

Moreover, in the light of medical knowledge properly presented to the commission that such a transfer of a streptococcic infection from a discharging wound as that found to have taken place in Caffrey's case was not only possible but highly probable, the court is of the opinion that the fact that the germs reached the face by external means and not through the system could not, as a matter of law, be said in itself to have broken the chain of causation.

Nor does the court think that Caffrey's conduct was such as to require a finding of negligence on his part. He was, of course, under a duty to use reasonable care to restore himself to health. But if he conducted himself as would a reasonably prudent person in his situation and circumstances, and innocently enhanced the original injury, it was within the province of the commission to find that the

original cause continued to the end and accomplished the final result, and was therefore the proximate cause. He might have had free treatment at the hospital maintained by the corporation for its employees, but he chose instead to remain at home and treat the foot himself with witch hazel and iodine. In the light of subsequent events, this was an unfortunate decision. The court is, however, unable to say as a matter of law that the commission was bound to find that, under all the circumstances appearing at the time, it was a decision so unreasonable and imprudent as to amount to a breach of his duty to use due care to restore himself to health.

Evidence Touching Testamentary Capacity

(*In re Swain's Estate (Iowa)*, 174 N. W. R. 493)

The Supreme Court of Iowa, in affirming a judgment holding invalid a will contested in this case, says that it is true that a man may be a drunkard and yet not necessarily incapable of making a valid will. He may be grossly immoral and filthy, and still not be of unsound mind in the legal sense of the word. He may be quarrelsome, or abusive, or profane, or eccentric, and yet not necessarily incompetent; but when very many of these characteristics are found uniting in a single character, and there is added thereto the testimony of experts that such a showing indicates a loss or decay of mentality, a verdict to that effect by the jury cannot be disregarded. Much of the complaint made by counsel in this case related to the refusal by the trial court to instruct the jury that evidence showing the testator had syphilis, that he frequented houses of prostitution, and indulged in other unclean and filthy practices, was immaterial and should not be considered as having any bearing on the question of his mental soundness. None of these objections were sound. It is true that no one of such acts, practices or habits is, as a matter of law, necessarily inconsistent with the theory of testamentary capacity; but this is not to hold that proof of such facts may not be considered with other facts as tending to show mental unsoundness. Men of sound mind do not, as a rule, so conduct themselves. With the normal man a sense of shame and regard for the decencies of life operate as some restraint on his conduct, and this is especially true with the normal man who has outlived his youthful follies and has left mentality enough to realize that his career is drawing to a close. Moreover, where the validity of a will is being contested, physicians who treated the maker of the will in his lifetime may be examined by the contestants of the will concerning knowledge so acquired by them in their professional capacity, under the Iowa decisions that it is not a violation of professional confidence protected by the Iowa statute.

Infant and Child Mortality.—The material for Schwarz's paper was taken from the social histories of 10,000 families. In 6,968 families there were 27,711 pregnancies, including miscarriages and stillbirths, an average of 3.9 per family. Of these 27,711 pregnancies, 2,239 were miscarriages and 413 were stillbirths; that is, there were 3.6 live born children to each family. The total number of deaths under 1 year of living births were 3,232. From the first to the eighth year there were 1,081 additional deaths, or a total of 4,313 deaths of living births. Taking all the deaths up to 8 years, including miscarriages and stillbirths, of the 27,711 pregnancies, 6,965 babies, or 25 per cent., died. The miscarriage rate in these families was 80.7 per thousand of all pregnancies and 89.3 per thousand of living births. The infant death rate (up to 1 year of age) in this group of families was 128 per thousand living births. A contrast to this figure is the death rate of 70 per thousand in this same group of families of only those of their children who, during the ten years, were under medical care. This figure, which shows a saving of 58 infants per thousand living births, proves conclusively what supervision, education and care can accomplish. The child death rate (up to 8 years) reached 172 per thousand. In other words, 172 out of every thousand children born alive, died before they reached the age of 8 years. The stillbirth rate per thousand total pregnancies was 14.9, and per thousand living births it was 16.4. The death rate, in early infancy, of children of native born parents, greatly exceeds that of the foreign element. The miscarriage rate is greatest when both parents are native born and least when both parents are foreign born. The literate have more miscarriages than the illiterate. There were 358 literate families with an infant mortality rate of 111 per thousand born, and 133 illiterate families with an infant mortality rate of 172 per thousand born. It does seem that education is a very important factor.

Use of Sodium Cacodylate in Athreptic Infants.—Six athreptic infants were selected by Clarke and Dow for study. A von Pirquet and a blood Wassermann from each infant proved negative. A routine urine examination yielded similar negative results. Eight injections of sodium cacodylate were given in all, at intervals of four days. All injections were given intramuscularly and hypodermically. The youngest infant, 6 months old, received one-quarter grain, as an initial dose; the oldest, 15 months old, three-quarters grain. The dosage was gradually increased till the youngest was receiving three-quarters grain and the oldest 1 grain. The maximum dose at any one time was 1 grain. A blood examination was done on all the infants before the injections were begun. A second examination was done after two injections, and a third after the last injection. The red and white cell count remained nearly uniform throughout, nor was there any marked change in the differential count. There was, however, a striking increase in the hemoglobin in all the children. Three children showed an increase of five points; one child of ten points; one twenty points, and one twenty-five points. One child failed to gain in weight during the injections, but in the month succeeding gained 1 pound, 10 ounces. Three children gained approximately 2 pounds,

and two gained $1\frac{1}{3}$ pounds. These gains have been continued since stopping the treatment. They all improved in nutrition and seemed to be more hungry for their food when feeding time arrived. Therefore, the authors conclude that carefully graduated doses of sodium cacodylate, when injected hypodermically into infants, has no toxic influence.

Prognosis in Operative Cases of Hypertrophic Pyloric Stenosis.—Goldbloom and Spence analyze 163 cases in which a Rammstedt operation was performed. One hundred and thirty-one children recovered and thirty-two died, a mortality of 19.63 per cent. It was evident that the operation per se is, perhaps, the least important factor in the mortality. The condition of the baby at the time of operation is the most important factor. Fourteen babies died from collapse from one to three days after operation, and five died from general peritonitis. One child died of bronchopneumonia complicating whooping cough, and one child died from post-operative hemorrhage on the third day after operation. The remaining eleven deaths were from marasmus and occurred in from three to twenty-five days after operation. In all cases, then, except the seven in which death was due to complications, the fatal result can definitely be attributed to a state of inanition existing at the time of operation. The mortality in artificially fed babies is more than three times that for the breast fed babies. In infants weighing 7 pounds or less, the mortality was three and one-half times as great as in those who weighed more than 7 pounds. The mortality increases in direct proportion to the amount of weight lost previous to operation. The mortality for breast fed infants who had vomited less than four weeks and who had lost less than 20 per cent. of their best weight is almost nil. The fatalities which occur are due to accidents usually avoidable when the operation is done by a skilful surgeon.

Infection Route in Respiratory Tract.—The submucosa of the trachea contains a rich plexus of lymphatics, prominent everywhere and devoid of valves. At the bifurcation of the trachea anastomosis occurs with similar plexuses in the bronchi, and this phenomenon is repeated throughout the region of the cartilage-bearing bronchi. At the bifurcation of the trachea, as well as of the bronchi, there is drainage to the lymph glands and anastomosis with periarterial and peribronchial lymphatics. When the lymphatics are injected, the larger portion of the material is diverted at these bifurcations, but continuity of the lymphatic system in the tracheal and bronchial submucosae is demonstrable. Winternitz and his associates found that pneumococci introduced by needle puncture through the skin into the lumen of the trachea or by insufflation, provided the insufflation catheter damages the epithelium of the trachea, spread by way of the lymphatics to the lung. The lymphatics of the submucosa of the trachea, then, afford a direct pathway of infection to the lung. Although this lymphatic system provides a pathway for infection, it may also serve as a protective mechanism against pulmonary infection, for the drainage of the submucosa of the trachea and bronchi is largely diverted as the lung is approached to the protecting regional lymph glands.

Fate of Influenza Bacilli in Respiratory Tract.—Three strains of influenza bacilli introduced by Bloomfield in large amounts into the normal upper air passages disappeared very rapidly within from one to two days. In no case was a carrier state produced. In no case did any local or general pathologic process result from such inoculation. In five instances influenza bacilli isolated later than twenty-four

hours after inoculation were shown to be different strains from those introduced. Influenza bacilli were no longer viable after being suspended in saliva for twenty-four hours at 37 C. The rapid disappearance of influenza bacilli from the upper air passages is probably due to the combination of an unfavorable environment with the mechanical flushing processes at work in these regions. Bloomfield is of the opinion that the question of the persistence of influenza bacilli in normal throats cannot be finally settled until we possess accurate methods for differentiating various strains of hemophilic bacteria.

Muscular Work During Hypnosis.—In order to determine the effects of suggestion on muscular efficiency and record the findings objectively, a Mosso ergograph was used by Nicholson as the instrument best adapted to fulfil these requirements. Only those subjects were used who could be placed in the deepest hypnotic sleep—the state characterized by cataleptic rigidity. The records secured show that a very definite increase in muscular efficiency can be obtained by suggestion in the hypnotic state and that suggestions given even while the subject is fully awake influence muscular efficiency to some extent. The increased efficiency during hypnosis shows itself in three ways: (1) By an increase in the actual amount of work done. In fact, during the hypnotic sleep the capacity for work seemed practically endless. (2) By an increase in endurance. (3) By a decrease in fatigue, both subjective and objective. After work in the hypnotic sleep the subjects never complained of any fatigue, nor could questioning elicit any signs of fatigue, whereas after performing a much smaller amount of work in the waking condition they frequently complained of being quite tired and exhausted and always on being questioned stated they were fatigued. The records show the absence of any objective fatigue.

*Chemical Examination of Blood and Urine in Normal Pregnancy and in Toxemia of Pregnancy. J. R. Losee, New York.—p. 38.

Executive Management of a Clinic for Babies. E. L. Coolidge, New York.—p. 57.

*Blood Transfusion in Obstetrics. J. R. Losee, New York.—p. 65.

Chemical Examination of Blood and Urine in Pregnancy.

—The twenty-one cases investigated by Losee fall into four groups, normal pregnancy, preeclampsia, eclampsia and pernicious vomiting. In the diagnosis of eclampsia a large amount of albumin in the urine and a normal blood urea are the most significant laboratory findings. Although modern biochemical technic is of great scientific interest and has marked clinical value in some diseases, and, whereas, it has disproved such theories as the acidosis, the amino-acid, and nitrogen retention as a cause of toxemia of pregnancy, it affords little assistance in the daily routine of clinical obstetrics.

Blood Transfusion in Pregnancy.—Losee has performed this operation seventy-eight times on seventy patients suffering from the complications of labor. Sixty-one were done by the syringe cannula method and seventeen by the citrate method. There were fourteen deaths in this series and all but one was undoubtedly due to the disease from which the patient was suffering. The latter, which may or may not have been due to transfusion, occurred early in the series, was an emergency and no preliminary tests were made. There were thirty patients on whom the operation was performed for hemorrhage or hemorrhage and shock, twenty-nine who were suffering from postpartum hemorrhage and localized pelvic sepsis, seven who had either bacteremia, septic thrombophlebitis of the pelvic veins or general peritonitis and four with toxemia of pregnancy of the pernicious vomiting type. Of the thirty patients suffering from acute hemorrhage due either to placenta previa, postpartum hemorrhage, premature separation of the placenta, ruptured ectopic or ruptured uterus thirty-two transfusions were performed and six patients died. There were twenty-nine patients with anemia secondary to postpartum hemorrhage and localized pelvic sepsis on whom thirty transfusions were done. They all completely recovered although some of them seemed critically ill on admission.

Four cases of toxemia of pregnancy of the pernicious vomiting type have been transfused with two deaths but here again it is only a supportive measure.

Obstetrics and State.—Many enthusiasts for maternal insurance, according to McIlwraith, carry the idea to extreme lengths, advocating motherhood insurance or practically the state support of the mother. Extremes of this kind seem to lead directly to bolshevism. Among the insurance benefit which the state might assume, in his opinion, would be the provision of sterilized dressings, sheets, etc., for the accouchement, and in some cases for nursing and medical attendance. Then, too, the authorities should be the judges as to whether the patient should be confined at home or in a hospital.

Arsenical Poisoning Following Use of Arsphenamin.—Fifty-eight cases of delayed poisoning following the administration of arsphenamin and mercury were observed by the authors in military hospitals and in private practice. Forty-seven of these showed symptoms referable to the liver, namely: jaundice, decreased digestive power and liver atrophy. Eight of these were fatal and at necropsy showed marked atrophy of the liver. Dermatitis occurred in eight cases. Five were severe with marked exfoliation. Peripheral neuritis was observed in two cases. Albuminuria was present in over 50 per cent. of the cases. Edema was found in two cases. The onset of the symptoms seldom occurred until five weeks after the administration of arsphenamin had ceased. The earliest symptoms of arsphenamin poisoning of the liver were, bile in the urine, albuminuria, loss of appetite and jaundice. Dermatitis with atrophy of the liver occurred in one patient who received arsenic in the form of Fowler's solution, 5 minims, three times daily, for five months.

Primary Sarcoma of Mediastinum.—A woman, aged 34, had sudden onset of pain in the left chest; increasing dullness in the left chest and mediastinum; nonhemorrhagic pleural effusion, left side; heart progressively forced to right; increasing difficulty in breathing; stridor; paralysis of left recurrent laryngeal nerve; increasing weakness of voice; persistent and increasing cough becoming brassy in character; no sputum. Emphysema developed in the right lung. Two positive Wassermanns were apparently unrelated to the principal disease. Roentgen-ray examination showed a dense shadow in the left lung area. This proved to be caused by a mediastinal sarcoma, involving also the left lung, trachea and right primary bronchus.

Trichocephalus Infection Following Appendectomy.—In the case cited by Hannah, the symptoms of postoperative abdominal adhesion were simulated by a *Trichocephalus trichiuris* infestation. Discovery of these parasites resulted from examination of the blood smear, with reference to the eosinophilia. Helminthiasis previously had never been suspected, as no gastro-intestinal symptoms were evident. The patient had been operated on for appendicitis, hence it was at first believed that the symptoms were caused by postoperative adhesions.

New Skin Suture Material.—The suture material used by Ochsner is made by treating silk chemically so that the tissue cells cannot penetrate the meshes of the silk. In addition, it renders the silk smoother, a little stiffer with less of a tendency to snarl, in fact, overcomes all of the objections to silk as a coaptation suture without robbing it of any of its desirable qualities. This material is said to overcome all the objections which can be raised against other suture materials.

Twenty Years' Experience of Notification of Industrial Disease. T. M. Legge, London.—p. 590.

Treatment of Varicose Veins.—Forty-eight cases form the basis of Homans' paper on this subject. He points out that operative treatment to be efficient must permanently break the column of blood between the abdominal vessels, which have no valves, and the surface capillaries. If it accomplishes this, it permits the restoration of a considerable amount of surface venous circulation through small veins which have not been distended by the stagnation in the main venous channels. It does away with stagnant blood on the surface—blood which keeps pouring down the distended vessels and increases the work of the still normal deep veins. It thus removes veins which are worse than useless and affords real comfort, but as it does not restore the original surface circulation, it cannot be said to return the patient to an absolutely normal condition. In other words, a perfect surgical result may not make the leg as good as new. At the Peter Bent Brigham Hospital, the so-called Corliss stocking is used with good result as a form of palliative treatment. The so-called "jelly" bandage, which is nothing more than gauze permeated with a paste originally devised by Unna, is also useful.

Pressor Compound from Pituitary Gland. A. C. Crawford, San Francisco.—p. 81.

Physiologic Action of Iodin Fumes.—On the basis of the results reported in this study there seems to be no question that the fumes of iodine are absorbed from the skin and by the pulmonary tissue. The negative results reported in man when the fumes and tincture were applied to the skin, are said to find a probable explanation in the fact that the urine and saliva were not collected over a long enough period of time. As a result of fuming the skin with the vapors of iodine the iodine content of the thyroid gland is greatly increased. The increase in iodine is accompanied by a pronounced change in the histologic features of the gland which clearly indicate an absorption of iodine. Iodin fumes when inhaled are absorbed by the respiratory tract; for the excess of iodine appears promptly in the urine and the iodine content of the thyroid gland is invariably increased, accompanied by a corresponding change in the histology of the gland. The indiscreet use of iodine fumes for inhalation leads to respiratory disturbances characterized by a dyspnea due to an inflammatory reaction in the lungs as result of the irritating action of the fumes. When iodine fumes are inhaled in quantities greater than 18 mg. per kilogram body weight, the animal dies within twenty-four hours from acute pulmonary edema. Intratracheal administration of iodine fumes leads to a temporary moderate rise in blood pressure and acceleration in the rate and increase in the amplitude of the respiration. The temporary rise is followed soon after by a more pronounced fall in the arterial pressure from which the animal partially recovers. After maintaining this pressure for a more or less prolonged period of time, the arterial pressure drops quite quickly. It is during this period that the signs and symptoms of acute pulmonary edema become quite marked. The respiration decreases in both rate and amplitude and ceases while the heart in the majority of instances shows a decided vagal inhibition.

The cause of death is an acute and rapidly developing pulmonary edema involving chiefly the basal portions of the lung. The edema supervenes more rapidly in animals having respiratory disease (tracheitis and bronchitis of beginning distemper) than in normal animals. It is clear therefore that the administration of iodine fumes by inhalation is a dangerous procedure. Such administration in persons with pulmonary disease is absolutely contraindicated.

Action of Gum Acacia on Circulation.—It is claimed by Bayliss that a solution of gum acacia of 6 or 7 per cent. in 0.9 per cent. sodium chlorid is capable of effectively replacing lost blood, unless the loss amounts to more than 75 per cent. of the blood volume. Hence its use in hemorrhage from various causes, whether from injury, disease or in operations. It has no chemical or druglike action and can be used in large quantities. It can also be used with benefit when the blood volume is reduced owing to removal of a part from effective circulation by stagnation in the capillaries, as happens in wound shock, traumatic toxemia and probably in similar conditions. In such cases, its primary object is to maintain a normal circulation until the toxic products are eliminated from the blood, while the blood out of circulation is restored to use. Neither gum nor blood has any permanent effect when the blood vessels are deprived of control by the vasomotor centers. Gum acacia does not produce anaphylaxis nor hemolysis. Nor does it agglutinate the blood corpuscles in man, although it does so in vitro in the case of some cats. This latter phenomenon does not appear to occur while the blood is in circulation, and is not followed by hemolysis, even in vitro. The addition of gum acacia to fluids used for perfusion of organs is recommended on account of the relative absence of edema.

Effect of Mustard Gas on the Eyes.—Reed found that concentrations of "mustard gas" of 0.0005 mg. per liter of air (1 part in 10,000,000), will produce visible reactions in less than one hour of exposure of individuals whose cutaneous resistance is relatively high.

Gradenigo's Syndrome.—This syndrome is characterized by an acute purulent otitis media, with or without mastoid involvement; intense pain in the temporal and parietal regions from involvement of the gasserian ganglion, and paralysis or paresis of the abducens nerve of the same side as the aural lesion. Such a group of symptoms occurring during the course of a middle ear suppuration or of an acute mastoiditis, before or after operation, may occasion considerable apprehension of an intracranial complication. In the cases reported by Maybaum these symptoms presented in more or less characteristic manner. In one case, the complication occurred two weeks after a simple mastoid operation, while the patient was making a satisfactory convalescence. Complete recovery followed without any further surgical intervention. In the second case, there was a history of an acute middle ear suppuration which had completely resolved at the time Maybaum first saw the patient, the syndrome had been present, with lessening severity, for a period of ten days; there was entire absence of signs or symptoms of mastoid involvement. A fulminant type of meningitis developed, from which the patient succumbed the following day.

Acridiflavine in Venereal Disease.—According to Rosen, acridiflavine has not answered the requirements of an ideal gonococcide clinically but it is a valuable addition for the treatment of venereal conditions. It would be an ideal gonococcus prophylactic. In the author's experience, the discharge was controlled in 61.36 per cent. of the chronic cases in from

one to six days' treatment. In 33.74 per cent. the character of the discharge was changed to a mucoid one, while in 4.9 per cent. of the cases it was without effect for twelve treatments. Two negative smears were reported in 60 per cent. of the chronic cases five days after discontinuance of treatment, i. e., no gram-negative diplococci were demonstrated. In 20 per cent. the discharge stopped but did not affect the organisms. In the other 20 per cent. of the cases the result varied, i. e., the first smear was reported negative and the second positive, or vice versa. Severe burning was complained of in 39.9 per cent. of all the cases, and was most intense in the acute cases.

Injuries to Skull. O. N. Meland, Warren, Minn.—p. 195.

Palliative Treatment of Trifacial Neuralgia.—Adson reports on 805 alcohol injections in 318 patients in addition to 203 other palliative operations, making a total of 1,008 palliative surgical treatments. Ninety patients have had the radical operation with complete relief, the remaining 228 are still seeking relief by temporary methods. Having personally divided the posterior-root in seventy-four cases of trifacial neuralgia, he is convinced that the radical operation is indicated in operable cases after one or two alcohol injections, in preference to continuing the palliative procedures indefinitely.

Protein Sensitization in Asthma and Hay-Fever.—A preliminary report is made by Sanford on the work done thus far on protein sensitization in asthma and hay-fever in the Mayo Clinic. Tests have been made on more than 800 patients during the past two years. Of this number, more than 500 were entirely negative in their skin reaction. The reactions of about 100 more were doubtful. The remaining patients, more than 200 in number, had definite skin reactions. Twenty-eight persons reacted positively to some of the animal emanations. The largest number of reactions was to horse dander. One hundred persons reacted to one or several of the proteins derived from foods. The greatest number of reactions was to egg white; eleven patients in all were sensitive to this protein. Twenty-five patients had marked positive reactions to grain. Twenty-eight patients were sensitive to vegetable proteins. This group, on the whole, is negative. Fruits, apparently, have little to do with asthma. In several instances banana gave marked reactions. Twice it was known to be a definite factor in producing asthma. In 365 tests to *Staphylococcus pyogenes-aureus* and *Staphylococcus albus* there was not a single reaction. Of the patients sensitive to ragweed and other fall pollens, fifty-two were definitely positive, thirty-six with hay-fever and sixteen with both hay-fever and asthma. The discussion of the treatment is reserved for a later report.

Hydrocyanic Acid Gas as Insecticide.—The quantity of chemicals required for 100 cubic feet of space to be treated is one-half ounce each of potassium cyanide and strong sulphuric acid. It is important to note that the potassium cyanide is pure. Under satisfactory conditions, where there is very little loss of gas by leakage from the room and when the room is empty, this will give approximately 110 parts of hydrocyanic acid per hundred thousand parts by volume of mixed gases in the room.

Antiscorbutic Property of Sun Dried Vegetables.—The experiments reported on by Shorten and Roy that three varieties of sun dried vegetables, viz., carrots, onions and cabbages, retain to some extent their antiscorbutic properties; while spinach is entirely lacking in this virtue.

Scurvy.—Hehir reports on the epidemic of scurvy among British troops and natives in Mesopotamia. He also calls attention to the fact that the Lister Institute has been investigating the etiology of scurvy carefully, and has found that germinating grains and pulses of various sorts contained antiscorbutic vitamins after the grain has sprouted.

Quinin in Malaria.—The whole subject of quinin and malaria, in Cornwall's opinion, requires and merits a properly devised and coordinated scientific enquiry, in order to determine whether quinin in harmless doses can act as a reliable prophylactic; if it cannot, then its use should cease; whether a primary attack of malaria due either to *Plasmodium vivax* or to *P. malaria* or to *P. falciparum* can be cured by doses of quinin which, compared with the harmful influence of the parasite, are relatively harmless to the patient; whether any useful purpose is served by dosing a patient with quinin between his relapses; whether any other chemical combination can be found which is able to destroy the parasites of

malaria without at the same time exerting a seriously harmful effect on tissue cells.

Quinin in Malaria Relapse.—Curjel is firmly convinced that some form of quinin appears to be the drug indicated for the treatment of malarial relapse. The exact mode of administration is immaterial, nor does there seem to be any advantage in excessive doses.

Detecting Fecal Carriers.—The method described by Liston and Gore is one which can be used by the general practitioner, provided he secures some ordinary agar slopes, a graduated pipet marked in fiftieths of a cubic centimeter, a feces emulsion tube, two platinum loops, some high titre agglutinating serum and a glass plate with hollows or some watch glasses. A little sterile water or physiologic sodium chlorid solution will also be required, together with an alcohol lamp, some slides, stains and a microscope. The details of the method are given.

*Method of Suturing Pillars of Fauces. T. Guthrie.—p. 102.

Origin of Quick Phasis of Vestibular Nystagmus. A. Rejo.—p. 103.

Tuberculous Otitis Media.—Among seventy-nine cases of chronic suppurative otitis media in which the causal condition was noted, Guthrie found thirteen cases of tuberculous origin. The mode of feeding was noted in eleven cases and in nine of these unboiled milk was used. Hence, it appears probable that the tuberculous infection is primarily implanted in the nasopharynx, whence it is conveyed to the middle ear by way of the eustachian tube.

Suturing Pillars of Fauces.—Guthrie passes a curved slot-eyed needle from behind forward through the posterior pillar, then, if thought necessary, through a thin layer of the tissue lining the tonsil fossa, and finally through the anterior pillar. The suture having been engaged in the slot of the needle, the latter is withdrawn and the suture disengaged and tied.

*A Large Ureteral Calculus Associated with Pyonephrosis. R. L. Ley.—p. 767.

Rupture of Aortic Aneurysm into Pulmonary Artery. W. E. Peacock.—p. 767.

Diagnosis of Pancreas Disease.—Garrod cites cases to emphasize that in the diagnosis of disease of the pancreas practically every sign, symptom, or test may fail and that the application of physiologic discovery at the bedside needs the cooperation of the laboratory and the ward.

Electrical Stimulation of Nerves at Operation.—In order to avoid needless operation, Burke says it must be remembered that conductivity is conclusive evidence of physiologic continuity of nerve fibers, as also is excitability below the lesion. Improvement in conductivity or in peripheral excitability following immediately after neurolysis is suggestive of only slight compression and possibly chemical nerve-block. Absence of conductivity and of excitability, even after neurolysis, is not conclusive evidence of division, but is probably an indication of fairly severe nerve disturbance.

Anaphylaxis Caused by Antitetanic Serum.—The case report by Gurd and Roberts is that of a healthy man who collapsed following the hypodermic administration of a relatively small dose—5 c.c.—during life identical with those which occur in anaphylactic shock in the dog, and with necropsy findings typical of those which are found in the guinea-pig.

Hydropathic Treatment of Malaria.—Eighteen soldiers had had lengthy consecutive courses of quinin treatment for chronic malaria without results. Zangger discontinued the quinin and gave the patients tepid "half baths." The arms, legs, and chest of a patient lying in a bath half filled with tepid water (82 F.) are rubbed for five minutes in the water then dried, and the patient is put to bed. Ambulant cases can rest for an hour and then return home. These baths were repeated three times a week for from three to four weeks, the average of baths per patient being eight. The malaria came to an abrupt termination within 10 days. During five weeks only five attacks were noted, and all the eighteen cases except one, who had one single slight feverish attack, were free from fever for the year during which they remained under observation.

Large Ureteral Calculus.—The stone in Ley's case was 3 inches in length and 4 inches in circumference. It weighed 2 ounces, 2 drams.

*The Phlebogram in Complete Arrhythmia and in Tricuspid Insufficiency. P. Schrumph (Geneva).—p. 529.

*Mechanism of Double Crural Sound. C. Pezzi (Pavia).—p. 547.

The Phlebogram in Complete Arrhythmia and in Tricuspid Insufficiency.—Sphygmographic and electrocardiographic researches combined have led Schrumph to the conclusion that serious cases of insufficiency of the tricuspid valve are nearly always accompanied by complete arrhythmia; most cases of complete arrhythmia, however, are independent of any insufficiency of the tricuspid valve.

The Mechanism of the Double Crural Sound in Aortic Insufficiency.—On the basis of his own independent investigations, Pezzi opposes the view advanced by Traube in 1867 that the double crural sound is a characteristic symptom of aortic insufficiency, and corroborates the opinion of Dagnini that it is a phenomenon of mixed, that is to say, of arterial and venous origin. Pezzi has never found it present in aortic insufficiency that was perfectly compensated. He has observed it only when there was more or less manifest myocardial insufficiency.

Typhoid Bacillus in Fixation Abscess in Typhoid. Damade.—p. 153.

*Chromic Acid in Fusospirillar Infections. W. Dubreuilh.—p. 153.

Clinical Forms of Hydatid Cysts of the Lung.—Creux remarks that there is scarcely any physical or functional syndrome of the lung that these cysts may not realize. He therefore thinks that a division into differentiated semeiologic types would have value for the physician who is called on to give his opinion in a case of pulmonary echinococcosis that he has had an opportunity to observe only a limited time: namely, the latent type, the pseudotuberculous type, the pseudopleuritic type, the type simulating intrathoracic tumor, and the suppurative type. Creux gives six case reports in illustration of these various types. This classification would have the effect of inviting the aid of roentgenologic, serologic and hematologic methods in solving the doubtful problems, and thus the clinician would be put on the right track leading up to appropriate and successful therapy.

Chromic Acid in the Treatment of Vincent's Angina and Other Fusospirillar Infections.—Dubreuilh recommends in Vincent's angina and in analogous infections a saturated solution of chromic acid, applied with a firmly twisted cotton swab. The oxidizing power of the chromic acid is such that if the solution is fresh and one does not use the swab at once after moistening it in the solution, it will begin to fume and the cotton will be found to be carbonized. The swab should therefore be barely moistened and not allowed to accumulate superfluous liquid. The ulcerations are rubbed rapidly and vigorously with the swab so as to detach

mechanically the false membranes and to bring the solution in direct contact with the ulcerated surface. The patient should also be allowed to rinse out his mouth at once, but should be cautioned not to swallow any of the saliva mixed with the acid. Occasionally it may be necessary to make a second application about the fourth or fifth day.

*Renal Syndrome with Asystolia. O. Josué and Parturier.—p. 221.

*Trophedema in the Insane. E. Coulonjou and others.—p. 230.

Disturbances in Kidney Functioning with Asystolia.—Josué and Parturier have published a number of articles on what they call the renal syndromes of asystolia, and here explain the mechanism by which oliguria of cardiac origin entails uremia and edema even when the kidneys are sound. The elimination of waste through the kidneys is defective because there is not enough water pumped into the kidneys to rinse out the waste, and the water stagnates and accumulates in the tissues. The symptoms may indicate uremia from serious kidney disease but under digitalis the whole train of symptoms subsides. The Ambard urosecretory index may be misleading in oliguria from asystolia, as also other tests of kidney functioning. The heart action should be brought back to approximate clinically normal and the oliguria be corrected by other means before the findings of these tests can be accepted as reliable. Albuminuria may be merely the consequence of the venous stasis, and it may disappear as this is corrected by the *polyurie libératrice*. The true figure representing the arterial pressure cannot be estimated during periods of asystolia and oliguria. There may even be asystolic hypertension, paradoxical as this seems. In asystolia, digitalis is always indicated, whatever the condition of the kidneys. But its task should be facilitated by getting rid of the water accumulated by the venous stasis; venesection and a drastic purge are the indispensable prelude to the digitalis. Nothing but milk should be allowed; with extreme oliguria, nothing but water; the amount of fluids should not be over 1.5 liter, and 100 or 150 gm. of lactose can be added. Small doses of digitalis are notoriously inadequate in the renal syndromes of asystolia, and the drug should be kept up until the energy of the heart seems to be permanently reestablished; one of his patients has taken a small dose daily for years. It is not necessary to restrict salt after the heart action has been restored to normal; there is no danger of return of the dropsy in these cases. The asystolia may be latent but still may imprint its stamp on the symptoms from lungs and liver as well as from the kidneys.

Trophedema in the Insane.—The trophedema in the two cases reported accompanied chronic mania; this seems to confirm the endocrine-sympathetic nature of the trophedema. It is possible that the factors responsible for the latter may be involved also in the causation of the mental disease.

The Blood Platelets.—Marchesini has continued his extensive research on the blood platelets, and here reports that the erythrocytes can all be classed in three groups, the stable, the partly stable and unstable, and that the early disintegration of the latter leads to formation of blood platelets out of their debris. The leukocytes serve merely as gathering centers for the debris of the unstable erythrocytes. This unstable group take stains instantaneously. The process of formation of platelets can be watched most instructively on the large erythrocytes of frogs and fowls. The unstable erythrocytes disintegrate more quickly under the influence of an aqueous extract of leeches.

*Hepatopexy. R. Mosti.—p. 1090.

Relations Between Influenza and Other Diseases. A. Bertolini.—p. 1100.

Fulguration for Cancroid of the Face. G. Paoletti.—p. 1103.

Operative Correction of Ptosis of the Liver.—Mosti devotes ten pages to a summary of the different methods in vogue for hepatopexy for total downward displacement of the liver, and comments on the disadvantages of all except the Santucci method. He reports the seventh case in which the latter has been applied, and extols the favorable conditions and permanent correction of the hepatoptosis without the slightest injury to the liver. A long curving incision is made from the sternal margin of the rectus abdominis sweeping down to four fingerbreadths below the costal arch and then up a little to the axillary line. The skin-muscle flap is turned back on the chest, and the peritoneum is incised just below the fold of the flap. The liver is then moved up into place and held there while the free lip of the incision in the peritoneum is rolled up on itself to make a kind of cord; this is encircled by three loops of stout silk about 3 or 4 cm. apart. Each silk thread is then passed through the right lobe of the liver, from the bottom to the top, about 2 or 3 cm. from the sharp edge, exactly to correspond to the location of the threads encircling the rolled-up cord of peritoneum. These threads are then drawn up and tied over the costal arch. The liver is thus supported from beneath and suspended from above, without any direct traction on the liver itself. The simple technic is shown in three illustrations. Mosti has found about thirty operative cases of total hepatoptosis on record, with nearly as many different technics as there were cases. He discusses further the clinical picture with sagging liver. In the case reported, the symptoms for a long time were merely from the stomach, but as the ptosis became more pronounced there was continuous and spasmodic pain, probably from traction of the heavy organ on its ligaments and from pressure on the solar plexus.

*Tactile Vocal Fremitus in Croupous Pneumonia. A. Gallotti.—p. 1.

*Uremia and Ureic Diuresis. Fornaseri.—p. 4.

Jan. 15, 1920, **21**, No. 2

Arsphenamin in Chorea. G. Salvetti.—p. 13.

Vocal Fremitus in Croupous Pneumonia.—Gallotti found the tactile vocal fremitus in fifteen patients with croupous pneumonia diminished during the second stage in 48 per cent. and intense in 17 per cent. In the first and third phases of the disease it was generally exaggerated. It is of autochthonous origin, that is, it occurs without the influence of the chest wall.

Uremia.—Fornaseri reviews the uremia with various acute and chronic diseases, and emphasizes that in treatment the diet should be poor in nitrogen and without salt. In the acute form, water, teas, gruels, stewed fruits and a small amount of milk are advisable. On water alone, the azotemia may increase, from autophagia. On a milk diet, also, the azotemia always notably increases. In chronic cases, cereals, vegetables, fruit and spaghetti may be allowed but only very little milk and meat. To promote elimination of the urea, measures to stimulate diuresis may include subcutaneous injection of artificial serum with 47 per cent. glucose or 0.5 per cent. lactose, injecting 10 gm. of the serum per kilogram of weight when the blood pressure is high, and 15 gm. when it is unduly low. Revulsives to the kidney region, purges and venesection are also useful.

*Intradermal Tuberculin Treatment of Pulmonary Tuberculosis in Children. J. Garcia del Diestro and B. Cordero.—p. 5.

*Polycystic Disease of Omentum. V. Juaristi and D. Arraiza.—p. 20.

Intradermal Tuberculin Treatment of Pulmonary Tuberculosis in Children.—Garcia and Cordero relate their expe-

riences with Mantoux' intradermal technic applied in systematic tuberculin treatment of children, in this instalment of their article, analyzing the cases in which no benefit was realized. These cases in which the method failed, proved useful guides for selecting other cases for the method and for the proper doses until highly favorable results could finally be counted on. To begin with, they state that dispensary treatment by subcutaneous injection of tuberculin has too many drawbacks and dangers, but the intradermal technic is free from these to a large extent, while the response to the intradermal injection is an instructive index of the individual tolerance at the moment, often rendering careful analysis of the temperature, weight, etc., unnecessary. The intradermal technic allows a tentative course of tuberculin treatment without danger for the patient, even when it proves ineffectual.

Cystic Disease of the Omentum.—The ruddy boy of 4 seemed healthy except for the enormous distention of the abdomen. A laparotomy revealed a mass of cysts, mostly united, and requiring the removal of the entire gastrocolic omentum. The conditions in the resected mass testified to the fetal origin of the cysts, some inflammation of the omentum during intra-uterine life having prevented the normal fusion of the layers, so that the inflammatory exudation held them apart and entailed the cyst production. Some of the cysts were as large as a fist, others only the size of a nut, and nearly all were joined together. Neither puncture nor the laboratory would have thrown any light on this case, Juaristi and Arraiza remark in conclusion, saying that if physicians would examine the peritoneum for themselves instead of trusting blindly to what is written in books—which copy one from the other—it would be better for all concerned.

Recurring Hemoptysis after Influenza. O. Clark.—p. 100.

Definition of Cenesesthesia and Kinesthesia. Vieira de Moraes.—p. 101.

Vomica with Pleurisy.—Cardoso has encountered two cases in which encysted pleurisy led to a vomica, the patient suddenly expelling from the lungs a mass of fetid pus and blood to a total of about 200 gm. This occurred at the eleventh day of the disease, during the night, in one of the cases. This patient was a woman of 40 and there had been scarcely any coughing before. Recurring hemoptysis and purulent expectoration kept up afterward for nearly three months, but recovery was complete by the fourth month. There was nothing to suggest a pulmonary process or syphilis, and the physical signs indicated interlobar pleurisy as well as the intense dyspnea, the hemoptysis and the intensely fetid breath and sputum. In another case the sudden expulsion of fetid pus and subsidence of symptoms was followed a week later by another vomica of about equal intensity soon followed by recovery; there must have been two sacs of pus in this case, he thinks. In still another case subcontinuous fever, cough and fine râles in the right lung suggested tuberculosis, but by the end of a month the extreme fetidity of the breath impelled closer examination, and a zone of dulness was found in the middle of the right half of the chest, at the back, a suspended area of dulness. This pointed to interlobar pleurisy, and puncture followed by thoracotomy led to prompt improvement of the symptoms from the pleura. If benefit is not soon apparent after the vomica, surgical measures should be considered, but the patient first mentioned recovered under symptomatic treatment alone, ergot, emetin, calcium chlorid, etc., with balsamics to promote expectoration. The hemoptyses were often alarming, but the good general condition and the final complete recovery justified the exclusive medical treatment.

Tonsillectomy.—Rohr gives an illustrated description of the technic and after-care, with special reference to the Sluder method.

*Operation on Nerves. M. Toussaint.—p. 3.

Treatment of Keratoconus. E. F. Montañón.—p. 7.

Influenza in the City of Mexico. J. León Martínez.—p. 11.

*Treatment of Neurosyphilis. A. Brioso Vasconcelos.—p. 15.

Operations on Ulnar and Median Nerves.—Toussaint describes the preferable technic for operations on these nerves as he applied it in a man of 30 whose right arm had been paralyzed since a gunshot wound eight months before. The operation included neurolysis, suture, and isolation of the sutured segment. The man is said to have now, two years later, complete functional use of his arm. The segments were isolated with two free flaps of adipose tissue, and Toussaint expatiates on the advantages of adipose tissue for this purpose and for arresting hemorrhage in operations on the liver, spleen, etc.

Treatment of Neurosyphilis.—Vasconcelos reviews the literature on this subject, and reports seven cases from his own practice in which he gave intraspinal treatment. He urges this direct treatment of syphilitic disease of the central nervous system whenever the spinal fluid gives a positive Wassermann, Pandy, Nonne, Noguchi or Lange reaction, and still more imperatively when several of these reactions are associated, as the patient is then a candidate for tabes or general paresis.

*Signs of Collective Degeneration in Colombia and Countries Similarly Situated. Miguel Jiménez López.—p. 227.

Hygiene of Milk. G. Arbeláez R.—p. 264. Concn.

Collective Degeneration of the Human Race in Colombia.—Jiménez states that Colombia is one of the three countries of the world with the lowest number of marriages (4 per thousand inhabitants), although the number of births was 31 per thousand in 1915. The mortality was 20.9 per thousand. The life expectancy is below the average, he says, and men at 30 have passed their prime, corresponding to the age of 45 in the temperate zones. His remedy is—in addition to hygiene and preventive medicine—to invite immigration on a large scale from peoples with characteristics opposite to those of the Latin races. He specifies in particular Switzerland, Belgium, Holland, Wurtemberg and the Tyrol as the countries where it would be best to seek immigrants.

Artificial Eyelids and Eye. R. Gil.—p. 837.

Etiologic Factors in Lacunae's Cirrhosis. F. Fernández Martínez.—p. 840.

Masked Tuberculosis in Children.—Garrahan relates that a tuberculin test, often applied up to four times, to 1,214 children at Buenos Aires, between 2 and 16, revealed that over 75 per cent. of the older children, between 14 and 16, were probably infected with tubercle bacilli. The children were apparently healthy and all of the poorer classes. Those brought up in asylums or other institutions showed 20 per cent. less tuberculous than those brought up in families. In infants with tuberculosis, the disease was never found entirely latent. Garrahan's experience thus differs from others' in this respect.

Origin and Treatment of Fibrous Degeneration of the Uterus.—Castaño presents an array of evidence to sustain the assumption that congestion in the uterus, of endocrine or infectious origin, is the initial stage of what progresses

to sclerosis, fibromatosis, parenchymatous metritis, etc.—all these are merely different stages of the one process. It begins with congestion and eventuates in sclerosis. This conception opens new horizons for treatment of all the eight typical uterine affections which hitherto have been regarded as separate entities. Local measures to reduce congestion, radiotherapy and kinesitherapy, with ovarian, thyroid or other glandular extracts to restore the endocrine balance, are the proper treatment for all stages and will benefit all but irreparable lesions. Treatment for syphilis may also be indicated.

Pulmonary Amebiasis.—Bullrich summarizes three other cases on record of nonsuppurating amebiasis in the lung, and describes in detail a case in his own service. The man of 43 had been clinically cured of dysentery with emetin six years before. After nearly three years, there had been a tendency to diarrhea. Then came sudden pain in the shoulder and it progressed, with coughing and sensations of something tearing loose in the lung, with bloody sputum afterward. There was also pain in the lung and liver and some fever, and the stools became dysenteric but no amebas could be found, no tubercle bacilli, and the Wassermann test was negative. Roentgenoscopy showed the apexes clear, but the right lung below cast a shadow, and the diaphragm was immovable. Under emetin, the temperature, stools, lung findings and general condition promptly returned to normal. Bullrich remarks in conclusion that the amebas probably invade the liver first, through the portal system. If they pass beyond the barrier of the liver, the lung is the next barrier they encounter.

*Action of Volatile Substances on Blood Pressure. S. Yamada.—p. 355.

*Antitrypsin in the Blood. S. Tachigara.—p. 437.

*Cord Anomaly in Knee Joint. T. Mayeda.—p. 507.

Action of Volatile Substances on Blood Pressure.—Yamada experimented, mainly on rabbits, with fifteen strong smelling and volatile fluids, including benzine and chloroform, and with fifteen essential oils, two perfumes, and with musk, camphor, phenol and tobacco smoke. They can all be classified according to the effect on the trigeminal or the olfactory nerve or on both combined. The reflex action from their effect in the nose raises the blood pressure but in the trachea depresses it. Simple mechanical or electric stimuli applied to the nasal mucosa seem to have a similar blood pressure-raising action, he relates.

Trypsin and Antitrypsin in the Blood.—Tachigara has been applying quantitative tests for antitrypsin in the blood in the healthy and in a number of pathologic conditions as he describes in detail, and reviews a bibliography of seventy-six titles on the subject.

Cord Anomaly in the Knee Joint.—Mayeda describes what he calls chordae cavi articularis genu and explains as an embryonal malformation of comparatively common occurrence. It is usually overlooked on opening the joint as no one examines the inner wall of the normal knee joint, and the cord bridging the cavity is not seen unless carefully sought for. Opposite conditions prevail in respect to the heart cavity, so that abnormal cords in the heart are readily recognized.

*Acute Dermatomyositis. Ridder.—p. 1211.

Pharmacology of Digitalis Leaves. G. Joachimoglu.—p. 1212.

Acute Dermatomyositis Simulating Trichinosis.—Ridder calls attention to the diagnostic value of the absence of hyperleukocytosis and of eosinophilia in a case of dermatomyositis, as this was the first definite indication that the case in hand was not trichinosis, which it closely simulated. That the spleen was not enlarged was also atypical. A diagnosis of dermatomyositis once established, treatment con-

sisted of profuse diaphoresis induced by light baths and hot air; inunction of the skin, and administration of stomachics and sedatives, with quinin in small doses. Ridder adds that an exact account of the anatomic findings and the course of the disease is to be given soon in a thesis by Behrendt.

*Aleukemic Myelosis. E. Keuper.—p. 118.

*Origin of Hemorrhagic Diatheses. R. Klinger.—p. 127.

Pulsation in the Auricle in Relation to the Venous Pulse.—Straub has been making a systematic study of this subject in a young officer left with a large defect in the chest wall after resection of the sternal ends of several of the right ribs for a suppurating gunshot wound. The bullet had lodged in the wall of the superior vena cava near its entrance in the right auricle. The defect was covered with skin and the action of the heart did not seem to be impaired, but the pulsation of the auricle was distinctly visible and could be compared with the venous pulse, throwing light on the mechanism and interpretation of the latter, as Straub explains.

Extrarenal Elimination of Cardiac Edema.—Heineke tabulates the findings in a number of extremely severe cases of edema from heart disease to demonstrate that instead of depending on the diuresis figures in estimation of the course of the case, the scales should be consulted. The patient's weight is the main criterion of the success of the efforts to reduce the edema. He does not agree with those who maintain that digitalis and strophanthin given for the heart disease are liable to induce contraction of the vessels in the kidneys, thus closing the outlet for the fluid through the kidneys. There may be other causes for the lack of effectual diuresis. The mobilization of the edema fluid by the action of the heart tonic on the circulation, and the consecutive hydremia, promote both the renal and the extrarenal elimination of the water. It is more difficult, however, for the circulation through the complicated system of glomeruli and tubuli to be restored to approximate normal than the circulation through the vessels in the skin. Hence the vessels in the skin may get to work sooner and act more efficiently than the vessels in the kidneys; there is no need to assume any constriction of the renal vessels to explain this delay in their functioning. In the cases of which curves are given, the extreme stasis in the vessels in the kidney was evidently exceptionally difficult to overcome. Heineke remarks in conclusion that he does not know of a single authentic instance on record of constriction of the renal vessels from the action of a heart tonic. His extensive experience, on the other hand, with cases of heart disease has convinced him that too often digitalis is given in inadequate doses and not kept up long enough and, above all, that there is too much dread of the intravenous route. He cites Meyer's successful case in which a digitalis preparation was given daily for a year.

Heart Block.—Eckstein has continued his research on the frog heart and in the clinic, and here states that the results have confirmed that the width of the impulse-conducting tract between the auricle and the ventricle does not modify the transmission of the impulse. The so-called partial heart block is not the result of any narrowing of the tract, but is due to functional modifications of the remaining elements. The power of the impulse is dependent on the number of times in which the elements of the tract can repeat a given process in a given unit of time, that is, the length of the refractory phase. This may differ in different parts of the heart and in the same part at different times. When two parts with a different length of refractory phase meet, irregularity of rhythm is inevitable. Hence allorhythmia is by no means always traceable to the impulse-conducting system, and its cause may be sought elsewhere in the heart. The cause may not be anatomic, as every kind of irregularity can be

induced by purely functional disturbances. The injurious influence causing the functional disturbance may reach the heart through the blood, or through the nerves, or may originate in the heart itself. The neurogenous can be distinguished by their modification under atropin. Over two pages of bibliography on disturbance in atrioventricular coordination are appended.

Aleukemic Myelosis.—Keuper reports three cases of what he calls aleukemic myelosis encountered in the course of four years. In one the condition was chronic, and the previously healthy man of 72 improved under roentgen treatment, the spleen became reduced in size and the patient has felt subjectively fairly well during the nearly three years he has been under observation. The sudden onset in the two other cases suggested an acute infection. The disease developed in the young woman immediately after marriage, beginning with intense headaches. The man of 32 had had some months before a period of lassitude, which suggested that the acute phase was the flaring up of a chronic disease. Both these cases terminated fatally in less than two months. The diagnosis long wavered between aleukemic myelocytosis and sepsis, the clinical picture resembling the latter until puncture of the spleen or bone marrow and examination of an excised lymph gland cleared up the case. Necropsy showed myeloid cells in the spleen and kidneys and leukemic infiltration in the spleen and kidneys in the woman.

Origin of Hemorrhagic Diatheses.—Klinger recalls experiments in which the blood platelets were removed from blood and the blood was then defibrinated and reinjected, but no hemorrhagic tendency was noted thereafter. He also recalls that the platelets normally do not stick together but only acquire this property as they lose their vitality. For these and other reasons he thinks that although hemorrhagic diatheses are usually accompanied by a reduction in the numbers of blood platelets, yet there may be no causal relation between these facts. He presents evidence to sustain the assumption of chemical factors as responsible for the hemorrhagic diatheses. The spaces between the cells forming the capillaries become more permeable under the influence of chemical injury (probably mostly hydrolytic) of the cells bordering these spaces (albumin or lipid membranes).

Determination of the Blood-Flow at Each Heart Beat.—Plesch describes his further development of the method of determining the volume of blood discharged during the phases of the human heart cycle by the amount of oxygen given off from the arterial blood. He claims to have perfected the method so that it can be applied to any person, under the most diverse physiologic conditions, during rest and work, and also under pathologic conditions. It can also be used for the testing of pharmacologic effects. The amount of oxygen consumed by the body must first be established, which is easily done by means of a short test of respiratory metabolism. The amount of oxygen held in the blood is then determined, which, Plesch states, can be done by means of a special type of hemoglobinometer just as accurately and with as little trouble and loss of time as a clinical determination of the hemoglobin content of the blood. Then the oxygen content of the blood in the right heart must be ascertained. Analysis of the peripheral venous blood will not suffice for this. For the determination of the oxygen content of the blood of the right heart Plesch has introduced what he calls the "Sackversuch" or rubber bag test. The subject to be examined is required to breathe

into and out of a rubber bag apparatus until, in accordance with the Henry-Dalton or the Boyle-Mariotte law, a tension equilibrium is established between the blood and the gas mixture in the bag. Based on an analysis of the air in the bag, a direct estimate of the oxygen content of the blood that flows from the heart through the lungs can be made. A portion of blood is saturated with alveolar air and another portion with the air contained in the bag. The difference in the oxygen content of the two samples of blood shows then the amount of oxygen per 100 c.c. given off or received by the lungs. He describes and compares with his method those devised by others for similar purposes.

Lefthandedness.—Griesbach states that owing to the fact that in lefthanded persons the speech center is located in the right hemisphere of the brain, instead of in the left as in righthanded persons, the custom of compelling them to write with the right hand, which work is for the most part associated with the speech center, causes them to struggle for years in order to transfer the speech center from the right hemisphere to the left. Lefthanded persons are not originally mentally inferior, as Stier maintains, but it is possible for them to become so through the above described attempt at a readjustment of the speech center. The result of their efforts may be that the speech center is not predominantly located on either side, which Griesbach regards as an unfortunate state of affairs, as it interferes with hemisphere differentiation during the process of its development throughout childhood and adolescence. In adults, a change from the right hand to the left, which sometimes becomes necessary through accident, is not marked by any central changes, as their unilateral hemisphere differentiation has become definitely fixed.

Diphtheria of the Umbilicus in the New-Born.—Henkel reports four cases of diphtheria of the umbilicus in the new-born, and states that this localization of the infection is not particularly rare. His experience with the condition has not been extensive but so far he has not found it a severe infection. The important thing is to recognize early the presence of diphtheria bacilli in order that mixed infection may not set in. If not recognized until late, more or less deep tissue injuries are sure to result, which renders the management of the case more difficult. When the diphtherial character of the infection is once recognized, the treatment must be entirely specific. Diphtheria antitoxin was administered in doses of from 500 to 600 units and was applied locally. In one case 4,000 units were administered in all. Powders and ointments are avoided. The infant should never be immersed in a bath until the cord has dropped off and the stump is dry. With this endemic appearance of diphtheria of the umbilicus, the cord and the umbilicus were treated daily with 96 per cent. alcohol. Other disinfectants are contraindicated as the skin of the new-born is so sensitive.

Morphin Poisoning and Apparent Death.—Joachimoglu, in discussing the case of apparent death in Berlin, an account of which appeared recently in THE JOURNAL, p. 837, expresses surprise that although the person when found in the park showed signs of life that were readily noted by laymen, the physician who examined the apparently lifeless body when brought to the hospital should have pronounced death as having ensued from morphin poisoning and should have neglected to make any attempts at resuscitation. In acute poisoning from morphin or other narcotics of the fatty series, Joachimoglu states, absence of respiratory movements, pulse and reflexes are by no means sufficient evidence of death, as was shown long ago by the animal experiments of Boehm, who chloroformed cats and waited until the manometer showed no pulse vibrations and until no heart sounds could be noted with the stethoscope, and then, at various intervals, instituted attempts at resuscitation. Cats were thus resuscitated when the heart had ceased to beat perceptibly for 7, 8, 9 and 19 minutes, and when respiratory movements had completely ceased for 10, 13, 14 and 24 minutes, respectively. As is well known, many persons apparently dead from chloroform poisoning have been resuscitated. The condition of the organism after acute poisoning may be compared to

that following drowning. In view of these facts, Joachimoglu considers it the imperative duty of the attending physician in all such cases to institute artificial breathing and to employ all other therapeutic measures (e. g., atropin in large doses) in an attempt to bring about resuscitation, and that only after long and energetic trials to restore heart and lung activity should the subject be pronounced dead.

Artificial Sterilization of Women.—Winter discusses what he regards as the indications for artificial sterilization. There seems to be an increasing misuse of the operation, which should be checked. Too much attention has been paid to the technic of the operation, to the neglect of the indications therefor. The fundamental idea or justifying basis for sterilization is to ward off the aggravating influence that pregnancy has on the course of certain chronic diseases. It is justifiable only when the life or health of the patient is seriously menaced. In exophthalmic goiter, although in from 6 to 7 per cent. of the cases one can expect serious complications, sterilization is not justifiable because strumectomy during pregnancy will ward off the danger just as well. In diabetes, relapses often result during pregnancy, and clinical experience would indicate that there are some cases of intermittent diabetes that do not subside after pregnancy; in such cases sterilization is justifiable. While tetany is sometimes seriously aggravated by pregnancy and fatalities are recorded, this is so rare that it can not be taken as an indication for sterilization. Dementia praecox is the only psychiatric disease that may necessitate sterilization. In chorea gravidarum, sterilization is strongly indicated if in earlier pregnancies grave and life-endangering symptoms were manifest. In neuritis of the optic nerve sterilization should be performed if after pregnancy the disease does not respond to treatment and atrophic conditions begin to develop; otherwise later pregnancies may lead to permanent blindness. Winter opposes sterilization in hysteria and neurasthenia, which many physicians recommend and carry out on the ground that the patients have been worn out by numerous pregnancies and the ever growing cares of the household. He thinks the husband should bring the desired relief through continence exercised for a time or means to prevent conception. In tuberculosis and in heart disease, sterilization is indicated in the most severe cases, as Winter explains in detail. In some severe complications of chronic nephritis sterilization is recommended. Owing to the fact that the mortality rate from cesarean section has been reduced to 1.5 per cent. (transperitoneal) and to 2.4 per cent. (extraperitoneal), a narrow pelvis is not as strong an indication for sterilization as formerly, but may be such still. Sterilization naturally presupposes consultation between two or more physicians and the consent of both spouses.

- *Chyle Cysts. V. Hoffmann.—p. 137.

Plastic Operations on the Skull.—Eight cases are described and the advantages of utilizing bone tissue from the vicinity to close the gap are emphasized.

Tuberculin Tests in Surgical Tuberculosis in Children.—Duthweiler analyzes her experience with 8 cases of tuberculous spondylitis, 3 suspects, 7 of a tuberculous process in the knee, 4 in the elbow, 3 of the hip joint and one suspect, and 6 others with tuberculous processes elsewhere. In the 28 cases in which the diagnosis was beyond question, only 6 responded with a positive reaction to the subcutaneous injection of tuberculin, and the focal reaction proved unreliable both when positive and when negative. None of the children seemed to have been injured by the skin Pirquet test done with small doses, and the response to this was constantly positive in the above 28 cases.

Ileus During Wartime.—Reusch reviews the experiences with ileus during the last five years at Würzburg and comments on its increasing prevalence of late years, the number of operative cases having increased from five in 1912 to twenty-nine in 1918.

Rupture of the Mesentery.—Duhs reports two further cases of isolated rupture of the mesentery from abdominal contusion, with fatal outcome in one case. The other patient recovered after resection of the stretch of mesentery involved and the 15 or 20 cm. segment of attached intestine. The other patient had recovered after suture of the tear in the mesentery, and seemed to be well for nine months except for occasional hematuria. Then he developed ileus, and necropsy showed circular stenosis of the stretch of intestine corresponding to the injured portion of the mesentery, and the latter had shriveled to a certain extent. Necropsy also revealed cicatricial changes in one kidney suggesting that the kidney had been ruptured at the same time.

Chyle Cysts.—Hoffmann reports a case of a large chyle cyst, and has found four others in his hospital records. He explains them as cystic lymphangiomas—tumors connected with malformations.

- *Regional Anesthesia for Goiter Operations. D. Kulenkampff.—p. 246.
- *Wire Versus Nail Extension. K. Ansinn.—p. 249.

Operative Treatment of Contracture of the Flexor Muscle of Great Toe.—Kleinschmidt describes the causes of contractures of this nature. A frequent cause during the war was immobilization of the foot for too long a time following gunshot injuries. In peace times the contracture is not so common. The clinical picture of the condition as seen in ten different cases was as follows: The ankle joint and the other joints of the foot, if they were not directly implicated in the fracture, showed only a moderate degree of stiffness, but the first metatarsophalangeal joint was fixed in a more or less flexed position. Any attempt at dorsal flexion met with stubborn resistance. The Payr operation for this condition consists in removing the sesamoid bones from the joint capsule and correcting adhesions. In five cases their removal relieved the condition and gave rise to no functional disturbances.

Local Anesthesia and the Technic of Goiter Operations.—Kulenkampff endorses Härtel's simplified technic for regional anesthesia in operations on the neck. He and his associates have used it for more than a year in over 100 cases and have yet to note any bad results. Kulenkampff recently has still further simplified it and used this technic in about fifty of the cases. The mastoid process-clavicle line is determined and following this line (the patient's head being turned away), with the palpating finger tips along the posterior border of the sternomastoid, and pressing fairly hard, the transverse processes of the cervical spine are located. A wheal is produced on both sides of the cervical spine at the junction of the upper and middle thirds. A needle 3.5 cm. long is inserted at one of these points and pushed directly downward into the tissues, thus coming in contact at a depth of from 1 to 2 cm. with the transverse process of the third or fourth cervical vertebra. The operator then cautiously goes on past the anterior border of the transverse process and for 0.5 or 1 cm. deeper. If no blood flows out of the needle, the syringe is attached and several drops

of the anesthetic solution are injected; the syringe is then removed and he waits to see whether a clear fluid will flow out of the needle. Often three or four trial injections are necessary before a clear fluid is returned. After securing a positive result, 50 c.c. of a 0.5 per cent. solution are injected without changing the position of the needle. The same procedure is followed on the other side. For the last two syringefuls (of 10 c.c. each) it is well to withdraw the needle partially and inject its contents just beneath the skin. Even large substernal goiters associated with severe dyspnea have not caused the slightest trouble when the above described technic has been employed. The regional anesthesia is as complete as with Härtel's multiple injections.

Wire Versus Nail Extension.—Ansinn prefers wire extension to nail extension for the alleged reason that it performs the same service and is associated with less danger from infection and formation of fistulas.

*Urobilinuria and Urobilinemia. H. Strauss and L. Hahn.—p. 193.

Urobilinuria and Urobilinemia.—Strauss and Hahn state that as urobilin is a normal ingredient of urine, it is also present in every blood serum, and its presence can be shown provided a sufficiently large amount of blood serum is taken for examination. Since urobilinuria denotes a physiologic condition, this term should not be used to designate an excess of urobilin in the urine; hyperurobilinuria is the proper term for this. The amount of urobilin in the blood varies greatly. It could not be found in normal persons in less than 48 c.c. of serum, so we might speak of a hyperurobilinemia when urobilin is found in a certain minimal quantity of blood serum.

*Rabies. W. Hamburger.—p. 717.

*Protein Therapy. E. H. B. van Lier.—p. 725.

Early Artificial Rupture of the Membranes.—Wijsenbeek compares the experiences at the maternity in Utrecht, where the bag of waters is spared as long as possible, with those at the maternity of Leyden where it is the routine practice to rupture the membranes early. In both series there were a number of cases in which delivery was abnormally prolonged; the rupture in itself does not seem to influence this. But the disadvantages in such cases of the membranes being ruptured is evident.

Prophylactic Treatment of Rabies.—Hamburger comments on the great increase in the number of cases of rabies in France and Belgium during and since the war. In the Netherlands, the burgemeester supplies money for traveling and other expenses so that prophylactic treatment for rabies is within the reach of every one free of charge. But the country has long been free from rabies until recently when a number of patients from the eastern provinces applied for treatment. In comparison with smallpox vaccination, the

antirabies treatment has the drawback that it is applied, not to the healthy, but during the incubation of the disease.

Protein Therapy.—Van Lier analyzes the extensive literature of the last few years for and against parenteral injections of milk. He relates that the *Deutsche medizinische Wochenschrift*, No. 20, 1918, had an article by Müller extolling the harmlessness of the injections as he had been making them for two years, and on another page an account by Lubliner of fatal anaphylaxis from this cause, the robust girl dying from anaphylactic shock a few minutes after an injection of milk, eight days after a previous series of injections had been borne without mishap. Oppenheim has also reported a severe anaphylactic reaction after injection of milk the seventh day. The injections should be made with all the precautions of serotherapy, and van Lier suggests that it might be better to use horse serum or other source of protein, adding a little dextro-albumose at need, or some simple solution of albumin, instead of milk.

*Gastric Secretion in Young Children. A. T. B. Jacobsen.—p. 773.

*The Parathyroid Glands. H. Bergstrand.—p. 791. In German.

Gastric Secretion in Young Children.—Jacobsen tabulates the findings after the Ewald test meal in twenty-five children, between 1 and 5 years old, with apparently normal digestive apparatus, and in six children with acute and twenty-four with subacute or chronic gastro-intestinal disturbance. The stool findings are also tabulated. These experiences testify that in children of this age the secretion of hydrochloric acid and of pepsin is not so strong as in adults, even in health. The congo and other reactions are weaker. With gastro-intestinal disturbance, achylia or hypocholia was found in about 75 per cent., but conditions returned to approximate normal as the gastro-intestinal disorders were cured. The stomach seemed to share in the presumed catarrhal condition in the bowels. He has been very successful in treatment with a milk and gruel diet after a few days of raw oatmeal soup following twelve hours of restriction to water during which the child was given 5 gm. of castor oil. Then one-fourth liter milk; a day or two later, one-quarter liter milk gruel; then one-half liter milk, one-quarter liter milk gruel and one-half liter water gruel, after which were allowed rusks, porridge, sweet sago soup, minced fish with melted butter and finally mashed potato, minced meat and tea. He ascribes the rapid benefit to the milk in these acute and chronic cases. Functional tests of the stomach proved to be superfluous, as the course was the same in the cases with and without anomalies in the gastric secretion. The article is in English.

Normal Anatomy of the Parathyroid Glands.—Bergstrand gives six pages of bibliography on the parathyroids and thirteen photomicrographs of the findings in parathyroids from adults, and discusses the minute structure and functions of the different elements. His conclusions differ in certain respects from those generally adopted.

Finska Läkarsällskapets Handlingar, Helsingfors

January-February, 1920, 62, No. 1-2

*Roentgenotherapy in Gynecology. O. A. Boije.—p. 1.

*Transient Hyperopia in Diabetes. E. Enroth.—p. 28.

Roentgen-Ray Treatment of Uterine Myomas and Hemorrhagic Tendency.—Boije reports that the hemorrhages ceased entirely in 83.7 per cent. of his 49 cases of uterine myomas, and the tumors shrank in 95.5 per cent. Only one case proved refractory to this treatment and no untoward by-effects were observed in any instance, or in 14 cases of uterine hemorrhages. In 5 of the latter complete amenorrhea was realized, and in the others the hemorrhages were restored to normal proportions. He warns, however, that polypous, submucosa and degenerated or gangrenous myomas are not adapted for radiotherapy. Operative measures also act quicker and more certainly on pain, but it may be wise to reduce the hemorrhagic tendency with radiotherapy and wait for the anemia to improve before attempting the operation.

He emphasizes that if myomas require intervention before 40 or 42, conservative enucleation should be the rule, but radiotherapy very cautiously applied might be advisable for younger women with ordinary menorrhagia and metrorrhagia. Between 40 and 45 it is better not to strive to arrest menstruation entirely. "The main point," he reiterates, "in radiotherapy is the selection of the cases for it. With the proper indications, the outcome is as favorable as with operative measures and with less risk."

Transient Hyperopia in Diabetes.—Enroth describes two cases of diabetes mellitus in a coachman of 48 and a farmer of 34 in which hyperopia up to 3 D developed suddenly in one and more gradually in the latter. It disappeared gradually in the first case by the third month; in the other the manifest hyperopia did not last more than five weeks. Changes in the lens seem to be responsible for the transient hyperopia, as he explains. Experimental glycosuria with examination of the sugar content and the refraction index in the fluids in the eyeball might throw further light on the question. He has encountered three cases of transient hyperopia in diabetes in the course of little more than two years, and has found twenty-seven cases on record in the literature.

Hospitalstidende, Copenhagen

Jan. 28, 1920, 63, No. 4

*Regulation of Neutrality in Epilepsy. A. Bisgaard and J. Nørvig. —p. 49.

Causation and Treatment of Epilepsy.—Bisgaard and Nørvig have been conducting research on sixteen epileptics in an institution, with comparative research on healthy persons—a total of several thousand investigations of blood and urine. They found a most remarkable increase in the ammonia content of the blood about three hours before an epileptic seizure or an epileptic psychic equivalent. Their charts show, as they say, "actually colossal" fluctuations in the ammonia content at these times. They were able to detect them by control of the ammonia content of the urine; when this began to go up, they examined the blood, and thus happened on the pre-seizure rise. They applied the van Slyke, Cullen, Folin, Kjeldahl and Hasselbach techniques in their study of blood and urine, hydrogen ions, etc. Their discovery of the increase in the ammonia of the blood in the psychic-epileptic status is, they say, the first well defined endogenous toxic substance yet demonstrated in connection with psychoses. The epileptic seizure seems to be a kind of anaphylactic shock or poisoning with albumin waste products. One man weighing 65 kg. had an amount of ammonia in the blood, just before a seizure, corresponding to 32 c.c. of normal solution of ammonia, that is, of a 1.7 per cent. solution. Besides ammonia, other toxic elements may be at work, but they are not able to bring on the seizure until the ammonia reaches a certain concentration in the blood.

Bisgaard and Nørvig conclude their extensive report with arguments to sustain the analogy between tetany and epilepsy, and their possible common etiology from deficiency in the parathyroid glands. The anamnesis of epileptics needs revision and the treatment, instead of being merely with sedatives to reduce reflex action, may advantageously attack the endocrine disturbance presumably responsible. The attempts published to date in this line have not been encouraging except with autotransplantation. Possibly the differences between donor and recipient may have interfered with the success of homotransplantation.

*Total Gastrectomy. H. Sundberg.—p. 145.

*Origin of Gastric Ulcer. R. Dahl.—p. 159.

Gastrectomy.—In the first of Sundberg's two cases there had been symptoms suggesting cancer of the stomach for several months in the woman of 64, but the glands around were not involved, and the stomach was freely movable. The woman is living in good health to date fifteen months after he resected the whole of the stomach except a small part of the cardia which was sutured to a loop of jejunum brought up through a wide opening made for it in the mesocolon. The loop was carried in a wide curve past the duodenum to which it was fastened. In the second case a still more complete operation was done; the jejunum loop had to be sutured to the esophagus. The condition was good after the operation but the woman of 65 succumbed shortly after to a recurring cerebral hemorrhage.

Origin of Gastric Ulcer.—Dahl presents evidence to show that aberrant cells of intestinal mucosa in the stomach and of stomach mucosa in the duodenum may be the points of lesser resistance which lead to the production of ulcers.

Ugeskrift for Læger, Copenhagen

March 11, 1920, 82, No. 11

*Polycythemia with Juxtapyloric Ulcer. H. I. Bing.—p. 337.

*Acute Orbital Disease Originating in Nasal Sinus. S. H. Mygind. —p. 342. Conc'n.

Immunity after Influenza. V. F. Møller.—p. 356.

*Radium Treatment of Uterine Cancer at Stockholm. I. Hansen. —p. 357.

Polycythemia with Juxtapyloric Ulcer.—Bing has heard of four cases in Denmark in which polycythemia accompanied duodenal ulcer, but he has been able to find in the literature only one article referring to this subject, Friedmann's report (American) in 1914 of twenty-five cases of a hitherto undescribed form of polycythemia and its possible relation to duodenal ulcer. Bing remarks, to begin with, that Friedmann's assumption that the normal limit for the erythrocyte count is 5 or 5.5 millions, is incorrect; the normal limit is 6 for women and 6.5 for men. He says further that Friedmann's account shows that the ulcers were juxtapyloric rather than strictly duodenal. Friedmann suggests as an explanation that an excess of epinephrin in the blood may explain both the ulcer and the polycythemia, citing Falta's statements that polycythemia developed in animals injected with epinephrin. Bing does not accept this explanation, and thinks abnormal losses of salt may possibly be the decisive factor. He reports a case of juxtapyloric ulcer in a man of 27 in which he found 7 millions erythrocytes in blood from the lobe of the ear and 8.2 millions in blood from the abdominal wall. Examination a week later, however, showed only 4.7 millions. In a woman with extreme retention in the fasting stomach, requiring the use of the stomach tube, he noted that the aspirated fluid contained large amounts of salt, from 2 to 9 gm. in the 300 c.c. of stomach content extracted each day. Salt might also be lost in vomited fluids. The output of urine ranged from 750 to 1,450 c.c.; the specific gravity was sometimes down to 1.003. The food contained usually little salt. The ash in the blood was 8.9 and the erythrocyte figure 7.5 or 7.1 millions; in blood from the skin of the abdomen it was sometimes 8.4 millions. The chlorid content of the urine ranged from 0.31 to 4.09, and of the blood from 3.5 to 4.1, with hemoglobin 128. These and other findings suggest, Bing states, that the excessive losses of salt may have been responsible for a relative polycythemia, restoring the balance in the blood. Perhaps the large amounts of soda which Friedmann's patients had been taking may have modified the chlorid content of the plasma.

Acute Orbital Disease Originating in the Nasal Sinuses.—Mygind reviews in detail the extensive experiences in this line at the Copenhagen eye and ear clinics, and urges the necessity for prompt and ample evacuation of the foci in the orbit and sinus, discussing the indications.

Radium Treatment of Uterine Cancer at Stockholm.—Hansen reports sixty-six patients with uterine cancer treated with radium over five years ago, mostly inoperable cases. About 6 per cent. died from intercurrent disease or have been lost to further investigation, but 27.3 per cent. are known to be living after the five year interval.

THE FUTURE OF OTOLARYNGOLOGY *

JOSEPH C. BECK, M.D.

CHICAGO

From the title of my address it might be assumed that I have been able by some magic influence to cast my eyes far ahead; that I have the great secret here transcribed, and that I am about to admit you into my confidence. If you will follow me, however, into the future, you will note that I am only judging it by my personal experience and observations, since I entered the practice of medicine exactly twenty-five years ago.

I have found it desirable to make two subdivisions of my subject: (1) development of an otolaryngologist, and (2) cooperation in otolaryngology.

DEVELOPMENT OF THE OTOLARYNGOLOGIST

A review of the history of the development of otolaryngology as a specialty would add considerable to the value of my presentation; but, for lack of time and space, it must be omitted. I wish, however, to say that we are much indebted to the pioneers, who have made it possible for those who followed to develop the branch into a real specialty. Yet, however great has been this development in the last twenty-five years, which many of us should feel it a great privilege to have witnessed, I believe we are at a threshold of even a greater step forward, namely, its recognition as a borderline specialty.

To meet the great demand for specialists, a number of graduate schools have made it possible for men to become operating or treating otolaryngologists, after a very short and inadequate course, and certainly without basic instruction.

Nothing has done more harm to the medical profession and to otolaryngology in America, in particular, than this result of imperfect pedagogics. The by-word "six weeks specialists" has been coined to apply to such practitioners, and the country is riddled with men with such training, doing not only otolaryngologic work, but often ophthalmologic work as well.

Fortunately, there were a fair number of men trained abroad, especially in London, Paris, Vienna and Berlin, who organized societies that set up high standards; and through their influence, many of these prematurely created otolaryngologists sought and secured adequate training. Again, the same societies are at this moment intensely interested in the problems of future development of the American otolaryngologist, and a permanent committee is at work. Having

the honor of being one of the members of this committee, and being personally very much interested in the subject, I desire to present a tentative plan for your consideration—a plan which is feasible and can be instituted immediately.

1. There should be organized a board of directors, selected from each of the five national otolaryngologic societies, namely, the American Otological Society; American Laryngological Association; American Laryngological, Rhinological and Otological Society; American Academy of Ophthalmology and Otolaryngology, and the Section on Laryngology, Otology and Rhinology of the American Medical Association.

Each society is to send five members, irrespective of having membership in one or more of the constituent societies.

2. This board of directors, having been selected somewhat in reference to geographic location, is to be divided into five sections: (a) East; (b) Middle West; (c) North; (d) South, and (e) Extreme West.

3. The division into the five sections is made to facilitate the work of the board throughout the year, as the board as a whole meets only once a year, preferably at the annual session of the American Medical Association.

4. The board of directors should have absolute control of the development of the otolaryngologist, acting as advisory both to the institutions of learning or training, and to the student. It should, furthermore, determine the fitness of the applicant for training as well as practice.

5. A student having satisfied the board of directors of his fitness to become an otolaryngologist, and having shown that in his undergraduate studies, as well as during his internship, he has given especial attention to this branch, as, for instance, seminar work or theses, etc., he is referred to a clinician, who will train him for one year. This corresponds to the second year of internship in a hospital.

It is assumed that the clinician has enough work for one or more such men, in order to give them the training and prepare them for the subsequent advanced study and development.

6. This advanced study or training should consist in a systematically carried out curriculum as prescribed by the board of directors.

A schematic schedule is herewith suggested:

1. Anatomy, normal and pathologic, of the nose and nasal accessory sinuses. From 10 to 12 (sixty hours) one month.

Use of wet, dry and microscopic specimens, including illustrations. The actual work for one such month's course may be thus exemplified:

A. Mornings: 1. Embryology and comparative anatomy of the nose and paranasal sinuses. Four hours.

2. Anatomy of the nose and paranasal sinuses from birth to adult life. Four hours.

* Chairman's address, read before the Section on Laryngology, Otology and Rhinology, at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

3. Anatomy of nose and paranasal sinuses in adult life. Eight hours.
4. Gross pathologic anatomy of nasal septum. Two hours.
5. Gross pathologic anatomy of middle and inferior turbinated body. Four hours.
6. Gross pathologic anatomy of the paranasal sinuses. Four hours.
7. Histologic pathologic anatomy of the septum, turbinates and paranasal sinuses.

2. Anatomy, normal and pathologic, of the pharynx, larynx, trachea, bronchi and esophagus. Wet and dry specimens, including microscopic slides and illustrations. From 2 to 4 (sixty hours) one month.

B. Afternoons: 8. Embryology and comparative anatomy of the pharynx, larynx, trachea, bronchi and esophagus. Four hours.

9. Anatomy of pharynx, larynx, trachea, bronchi and esophagus in children. Four hours.

10. Anatomy of pharynx, larynx, trachea, bronchi and esophagus in adults. Four hours.

11. Gross pathologic anatomy of pharynx, larynx, trachea, bronchi and esophagus. Four hours.

12. Histologic pathologic anatomy of pharynx, larynx, trachea, bronchi and esophagus. Four hours.

3. Anatomy, normal and pathologic, of the ear, including the mastoid process. From 10 to 12 (sixty hours) one month.

Use of wet, dry and microscopic specimens and illustrations.

4. Anatomy, normal and pathologic, of the brain ganglions and cranial nerves.

Use of preparations, gross and microscopic; also illustrations. From 2 to 4 (sixty hours) one month.

5. Diagnosis and surgical treatment, on the cadaver, of the nose and the nasal accessory sinuses. From 9 to 12 (eighty hours) one month.

6. Diagnosis and surgical treatment, on the cadaver, of ear, mastoid, brain and nerves. From 2 to 5 (eighty hours) one month.

7. Attendance in ambulatory clinic of ear, nose and throat, observation only. From 9 to 12 (eighty hours) one month.

8. Reports on work in the observation clinic in writing and illustrating with reading and reference to literature. From 2 to 5 (eighty hours) one month.

9. Ambulatory clinic, ear, nose and throat in a clinic service. From 9 to 12 (eighty hours) one month.

10. Report in writing and with illustrations, reading and reference to literature on work in the clinic. From 2 to 4 (sixty hours) one month.

11. Observation on surgical clinic in ear, nose and throat. From 9 to 12 (eighty hours) one month.

12. Report in writing with illustrations, reading and reference to literature of the work observed in the clinic. From 3 to 5 (sixty hours) one month.

13. Observation in major surgical clinic, especially head and neck surgery. From 9 to 12 (eighty hours) one month.

14. Report in writing and illustrations, reading and reference to the literature on work of that clinic. From 2 to 5 (eighty hours) one month.

15. Surgical clinic in ear, nose and throat in active surgical service. From 9 to 12 (eighty hours) one month.

16. Reports in writing with illustrations, reading and reference to literature, on the work performed at the clinic. From 2 to 5 (eighty hours) one month.

The important questions now to be answered are: Where is the student to get this instruction? How are they to be grouped? What financial arrangements will be necessary?

I stated at the outset that the plan was feasible and could be made use of immediately. Let me propose a trite example:

A student applies to the board of directors, let us say, from the Western Section (San Francisco). He will be informed by this board what credentials he must have. The board is in possession of the names of a number of clinicians, who have signified their willingness to take an applicant for a year. If the student has a preference and the preferred clinician is available, appointment is made accordingly. After one year of service with the clinician, he receives a certificate from the clinician signifying the type of

work performed, and he again applies to the board for advanced work. He will be informed that he may choose Harvard University, Pennsylvania or any university giving the course. At completion of each particular course he will receive from the instructor a certificate of attendance with grade for the work done. The actual expense of such a training cannot be stated, because it will vary with the necessary traveling, etc.; but so far as the first year of the training with the clinician is concerned, the student should receive the same compensation as an intern at the hospital, namely, board and lodging. The cost of the advanced work should be that which each university will demand. It has been customary for the American universities to make the minimum charge for any instruction.

Having completed the prescribed number of courses satisfactorily, he will return to the annual meeting of the board of directors and receive his properly accredited diploma, and he will be recognized as a thoroughly trained otolaryngologist.

While the courses outlined are perhaps not actually available at this time, and they are not absolutely required for a year, I am sure that arrangements can soon be made for them, and the results will be all we could desire.

The most difficult courses to secure in this country are the practical surgical training on the living; and if I may be permitted, I would suggest that until the clinical material is sufficiently organized for this work, the student may be required to go abroad for this portion of the work. I was authorized to state, by the clinicians of the University of Prague-Czechoslovakia, that any one who has had the preliminary training and is recommended by proper medical authority will be given ample opportunity to work on the living at their clinic. It is also quite likely that other European clinics will be soon ready to receive American physicians.

Being in possession of a proper general introduction from the members of the board of directors, the student now makes a tour of observation for four months. A list of large otolaryngologic clinics should be sent to each student. The length of time he shall spend at each place is left somewhat to the judgment of the student. At the conclusion of each visit he is to make a brief and concise report of what he has seen and heard.

It has been considered that perhaps the outline of what I term advanced training should precede the one year of practical work with the clinician; but after I had discussed the matter with several pedagogues in otolaryngology, it was thought best to do as advised above. The reason for this is that the student, having observed for one year the difficulties actually encountered, will be more eager to learn details. Also the question of appreciating subsequent teachers, when he makes the observation tour, comes into play.

Having completed his training and received his recognition as an otolaryngologist, he has yet a great deal before him toward development. In fact, it never stops and one is continually learning. He will have to decide whether he shall enter the practice independently or in association with one or more men in practice.

Speaking from personal experience, I shall advise everybody to become an associate. I have trained men and women ever since I have been in the practice of otolaryngology, and with few exceptions, these have found places as associates and have been, I believe, success-

ful. Furthermore, every otolaryngologist should join his local and national otolaryngologic society, take part in discussions, and try to do, as often as possible, some accredited work, and thus promote the advance of our specialty and develop into a real otolaryngologist. So far as the otolaryngologist visiting his colleges at home or abroad is concerned, I desire to state that the organization of an international society at the next international congress would be advisable. Membership in such a society would be accorded to any recognized otolaryngologist in his respective country, designated by a membership card. There need be no officers, dues or other expenses connected with such an organization. A member of the society, presenting such a membership card, should be entitled to all the possible professional courtesies, and given every opportunity to learn what his friend and colleague is doing. The idea of such a society would be, no need of special letters, etc., of introduction, nor any hesitancy on the part of the visitor to seek information. Besides, men would aspire to the recognition of an otolaryngologist, and the pretender would be denied rare privileges.

COOPERATION OF THE OTOLARYNGOLOGIST

With the establishment of the various specialists, there has developed such an epidemic of so-called group medicine or team work all over this country, that I have thought wise to call your attention to the possibility of this practice to cause more harm than good when thus applied. That group medicine is one of the greatest factors in benefiting the people and furthering science, there is no question; but the group must be competent. What I am objecting to is the pretension group of so-called specialists combining for commercial reasons and causing a lot of trouble by making false diagnosis, unnecessary and poor operations; therefore, my suggestion and outline of conditions or diseases in which otolaryngologists and the other specialists are simultaneously concerned.

We may divide society grossly into three great classes: (1) the wealthy; (2) the middle class, and (3) the poor. The relative percentage of these classes varies considerably, depending on the location, concentration and character of the district. The medical problems of these classes are by no means solved. However, the wealthy do not suffer, for their pecuniary resources command the necessary skill required. The poor are usually provided for in most communities through the great hospitals, which attract men of the highest medical attainment, who give their services free and without stint.

Those who belong to the middle class are by no means so fortunate. They cannot conscientiously accept the charity which is offered the poor, nor have they the means to secure the service which they desire and which the wealthy receive. They are hence often denied the medical attention in the varied and comprehensive manner required in the practice of modern medicine.

The great factor of this situation is the degree to which medicine has been specialized. While this specialization has been at times greatly overdone and often misapplied, the significant fact still remains that medicine as well as medical practice must be subdivided if any degree of expertness or efficiency is to be achieved.

In addition to otolaryngology, the recognized special branches in the practice of medicine are: (1) general

surgery; (2) orthopedic surgery; (3) internal medicine; (4) gynecology; (5) pediatrics; (6) neurology and psychiatry; (7) dermatology; (8) obstetrics; (9) ophthalmology; (10) genito-urinary diseases; (11) clinical laboratory, and (12) dentistry. Naturally, there is a great deal of overlapping in the work of these specialties, and many questions as to the best interests of the patient frequently arise. Furthermore, this condition of things is not always successful in getting the best values—to use a colloquial term—out of the physician's work. A study of these circumstances has convinced me that there is still much to be done before these enforced divisions of medicine can become sufficiently harmonized to be brought into a proper relation with one another.

Among the many relational questions that arise, one of the most difficult is to determine to which of the specialists the patient belongs, with respect to treatment. In other words, when shall a skin and venereal specialist treat a syphilitic nasal or throat case, and vice versa? My answer is, "Whoever knows most about the subject." Surely the skin and venereal specialist should be the man in charge, because no matter how well the local treatment is carried out, the patient will not recover unless his general specific medication is given in the most efficient manner. Yet if that patient has a laryngeal stenosis or a nasal sequestrum, he will require the service of a well-trained rhinologist and laryngologist to help him.

What, then, is the answer? Cooperation. I realize that there are other facts which must be considered, as the ability of a patient to pay the fees of two or more specialists instead of one, and the financial loss to the one who refers. Both these can be overcome. The former can be met by charging only one fee, except perhaps for the initial examination.

Financial loss cannot be considered when the patient's well-being is concerned; however, mutual reference of cases more than compensates for this. Furthermore, the practice of medicine in the future, in furtherance of the interest of humanity, will make the necessary adjustments in this regard to meet this situation.

1. *General Surgery*.—Considered regionally, this may be subdivided into: (a) oral and maxillofacial surgery; (b) brain surgery; (c) neck surgery; (d) chest surgery, and (e) abdominal surgery. In the first three divisions, otolaryngologists are called on to treat most of the borderline conditions. I have for over fifteen years published articles setting forth the reasons why that should be so, and I have considered that upper and lower jaw diseases, as osteitis, fractures and dislocations and tumors, are properly in the domain of the otolaryngologist. The various plastic reconstructions for congenital conditions, as cleft palate and hare-lip, or for those due to the loss of substances from disease and injury about the head and neck, are and have been well managed by the otolaryngologist.

Brain surgery is and has been a function of otolaryngologists for a great many years, by reason of the fact that three important surgical conditions follow as complications of suppurative ear and sinus diseases. I refer to septic sinus thrombosis, meningitis and brain abscess. The result of this is that the otolaryngologist performs many brain operations following his diagnosis, and he is correspondingly entitled to undertake the surgical treatment of tumors and other intracranial affections, such as gasserian ganglion

disease, meningocele, hydrocephalus, microcephalus and oxycephalus, as well as other ventricular conditions.

Several neck operations have for some time come under the dominion of the laryngologist, such as tracheotomy, laryngectomy and laryngostomy, as well as jugular vein and carotid artery ligations.

The thyroid gland and other neck tumors, as well as the glands of the neck, are still more or less under the management of the general surgeon; yet there is no special reason for this, as the otolaryngologist is fully prepared to undertake this work.

In chest surgery, the otolaryngologist is much concerned in lung abscesses, especially from the etiologic standpoint. Since tonsillectomies are being performed in increasing numbers, especially in adults under general anesthesia, there have been reported a fair number of lung abscesses. In this particular, however, the general surgeon is better prepared than the laryngologist.

Foreign bodies in the bronchi and lungs entering by way of the upper respiratory tract are responsible for a goodly number of lung abscesses, due usually to failure to diagnose or to remove them by way of bronchoscopy.

In the mediastinum we are concerned in esophageal conditions, such as diverticula, foreign bodies, strictures, abscesses and tumors, all of which are and have been best treated by way of the upper or pharyngeal route, by the laryngologist who is skilled in bronchoscopy and esophagoscopy.

The otolaryngologist comes in to relation with abdominal surgery in connection with the diagnosis and treatment of such conditions as gastric and duodenal ulcers and appendicitis, in which there may be a question of the source of a focal infection. It may even be impossible to determine whether one of these or a tonsil infection is the causal agent. In cases in which there is doubt, the tonsil operation which is attended with far less danger or discomfort should at least have the preference.

2. *Orthopedic Surgery.*—The orthopedic surgeons who recognize focal infection as responsible for many of the joint, muscle and tendon affections find it useful to have their cases analyzed with respect to the probable focus of the affection somewhere in the domain of the otologist and dentist. It is very discouraging, however, to note that orthopedists refer cases of bow-legs, clubfoot, ankylosis, etc., for operation on the tonsils.

3. *Internal Medicine.*—The cooperation of the otolaryngologist and internist is so important that I have found it necessary to have one associated constantly in the diagnosis of chronic septic or focal infection; it requires the most careful attention of the laryngologist and the internist to determine just where the most likely focus of the trouble lies. The disease classified as rheumatism, either arthritic, muscular or neural, is most frequently called into question, and there is no doubt that the proper attention to the infected tonsil, tooth, nasal accessory sinuses or middle ear is frequently followed by relief or cure.

It should not be forgotten that the internist, as well as the pediatrician or the orthopedist, sometimes errs in referring cases to the otolaryngologist for the removal of a septic focus. An instance of this sort was a case of alcoholic neuritis referred to me on the supposition that there was a focal basis in the tonsil. Kidney, heart and the vascular system are very fre-

quently involved from a focal infection, and the best management is through cooperation of internist and otolaryngologist.

Disturbances of the intestinal tracts are so frequently responsible for symptoms referable to the nose, throat and ear that I believe the otolaryngologist frequently treats these conditions by mistake, when they should be under the charge of an internist.

Under the same category may be placed the questions of diet, constipation and conditions resulting from disorders of the gastro-intestinal tract. These are so much in evidence in the daily work of the internist that they are his by superior knowledge and practice. On the other hand, unless the internist is on his guard, he will find himself endeavoring to relieve suppurative ear disease with labyrinthine fistula by attention to the stomach and intestine, the apparent location of the symptoms.

The lower respiratory tract, the bronchi and lungs are so frequently dependent on diseases of the nose and throat, especially the nasal accessory sinuses, that the interest of the patient cannot best be conserved unless both internist and otolaryngologist cooperate. Recurrent tracheobronchitis, asthma and bronchorrhea are most interesting subjects in this connection, particularly asthma, which recent investigations tend to show dependent on sensitization by protein poison due to disturbed action of the glands of internal secretion.

This brings me to the next class of diseases in which the internist and otolaryngologist must cooperate. Although much burdened by speculation, there are no doubt many positive findings that show the importance of the rôle played by the glands of internal secretions. Symptoms referable to the ear, nose and throat are common accompaniments, and it behooves the otolaryngologist to be well informed, so that he may cooperate with the internist in all such disturbances. The internist should understand how readily the rhinologic surgeon can operate on the hypophysis through the nose and sphenoid sinus, which may save the patient's vision and life.

There are no doubt many other conditions in respect to which the internist and the otolaryngologist must cooperate, such as the various anemias and diabetes which produce so many nose, throat and ear manifestations, which need not be particularized. It is easy in this connection for the otolaryngologist to err in the diagnosis. On the other hand, the internist may treat an anemia which is dependent on some nose, throat or ear infection as a chronic sinus or ear suppuration which he may think unimportant.

4. *Gynecology.*—The female genitalia, when diseased, may produce symptoms referable to the nose and throat. All are familiar with the swellings of the erectile or turbinate structures within the nose in cases of malposition, inflammation or fibroids of the uterus. Some laryngologists have been very successful in relieving dysmenorrhea by some slight cauterization of the anterior part of the septum nasi. I have called attention to the closer relation in chlorotic girls between infantile uterus and atrophic rhinitis. Grayson and others assert that a hypersensitive condition of the nose occurring during the honeymoon period may result from changes in the female generative organs.

5. *Pediatrics.*—The pediatrician and the otolaryngologist are very often associated, especially in acute

infectious disease, because the nose, throat and ear symptoms are so prominent and complications involving these organs are among the commonest and most serious results of the infections. While all well trained pediatricians recognize this, they hardly give them the attention they deserve. Thus, it is commonly observed that an acute otitis media or acute sinus affection is frequently allowed to extend into a subacute or chronic state without being properly attended. It is my belief that many chronic suppurative and non-suppurative ear and sinus conditions result from the neglected or undiagnosed cases of sinus and ear infections in childhood.

Great strides have been made in recent years toward the establishment of the diagnosis of sinus disease in children, and for this reason there is less excuse for permitting these processes to continue into adult life, making a cure impossible or difficult.

Pediatricians and otolaryngologists, and even the laity, recognize the importance of the removal of tonsils and adenoid tissue, when diseased, and have been convinced of the remarkable improvement that follows proper removal. It must be admitted that there has been perhaps a bit of overenthusiasm along these lines. I mean that there is a disposition to hold the tonsils accountable before an exhaustive diagnosis of the condition has been made. If the operation does not clear up the condition, both the pediatrician and otolaryngologist may be inclined to hold the tonsillectomy at fault, when in reality a mistake in diagnosis was made.

6. Neurology and Psychiatry.—In my practice I see more cases presenting symptoms referable to the nervous system than to any other special branch. I have roughly estimated that 33 per cent. and at times 75 per cent. of all cases under treatment are more or less related to the nervous system. The most pronounced symptom is headache. The analysis of a headache is in my judgment the acme of perfection in diagnosis. The next in frequency is pain about the head and neck. It is often spoken of by the patient as headache. These symptoms are referable to disturbances of the gasserian and sphenopalatine ganglion and their branches.

As already mentioned, intracranial complications of sinus and ear suppurations, as well as brain tumors are very frequently the subject for discussion between the neurologist and the otolaryngologist. But of all the conditions in which the neurologist and the otolaryngologist come into relation, none is so important as disturbances of the organs of equilibrium. The work of Bárány and his followers has been so developed that an actual fusion of the two especial branches has taken place in the formation of what is known as "neurotology."

Neurologists, in the main, have not shown the interest in this work that it merits, whether because they do not take the trouble to study it or because they doubt empirically that it has any value. At any rate, only a few neurologists in the country have cooperated with otologists to the extent that is justified.

There are quite a number of conditions presumably of exclusive concern to the neurologist, as cerebral syphilis, tuberculous meningitis, general paresis, dementia praecox, epilepsy, and the various mental states as mania, melancholia, manic-depressive insanity and hysteria, in which the symptoms of

dizziness and vertigo are present and in which the function of the cerebellum, stalk and semicircular canals should be studied.

7. Dermatology.—I have already mentioned that cooperation between the otolaryngologist and the skin and venereal disease specialist is essential. Syphilis, of course, is the most common disease in which both branches are concerned. Not until the Wassermann test came into use as a diagnostic measure, was it found how many syphilitic ear, nose and throat conditions there are; and, strange to say, there are still many cases in which there is a presumption of syphilis and in which a competent Wassermann reaction, either of the blood or the spinal fluid, is not made. I shall speak of the competence of the Wassermann test later, when I take up laboratory cooperation. I could spend a long time discussing examples of syphilitic conditions involving the nose, throat and ear, but it will suffice to say that in every possible case it will be well to cooperate with the dermatologist, especially in the general treatment. I find quite a number of otolaryngologists still refusing to employ arsphenamin, because intravenous medication is somewhat more difficult; and when they do employ it, they are not completely successful.

Lupus and epithelioma are frequently found in the regions of the nose and ear; and in this regard they require cooperation of the two specialists. Especially is this true at present when the therapy is mostly carried out by the aid of radium and the roentgen ray.

A very common and most difficult condition to treat is what we call eczema of the external auditory canal. I am confident that an incorrect diagnosis has often been made. I have one such case which I treated for four years as eczema. A dermatologist made the diagnosis of favus and treated it as such with a permanent cure in six weeks. While furunculosis, both of the external ear and vestibule of the nose, is fairly well treated by most otolaryngologists, the general subject of furunculosis is much more exhaustively studied by the dermatologist. The same can be said of the acne which at times involves the external nose and ear. The bacterial side of the question as well as therapy (vaccines) is important, and the dermatologists are much better qualified than the otolaryngologists in this subject at this time.

So many other rare skin lesions are found, also infrequently about the nose and ear, that I wish to lay special emphasis on the importance of cooperating with the dermatologist. On the other hand, I must express my surprise at the dermatologist who is treating frank nose and throat and even ear conditions without the cooperation of an otolaryngologist, just because he has made a Wassermann test and found it positive or even because the patient has other syphilitic lesions. I am sure that local treatment is entirely ignored. The wrong is twofold: first, a syphilitic patient may and does have a nonsyphilitic nose, throat and ear affection; and secondly, many syphilitic nose, throat and ear affections must have local treatment and even operations at times.

8. Obstetrics.—Otosclerosis is a condition which should concern the obstetrician, although it is of far less importance than ophthalmia neonatorum. The well known hereditary tendency of this disease, especially when both parents are affected, makes it an impor-

tant factor in the prophylaxis of deafness. Furthermore, during gestation, labor and lactation, deafness is greatly increased in the mother suffering from otosclerosis. I have had several cases of otosclerosis in pregnant women in whom in cooperation with the obstetrician we carried out the systematic treatment of hypodermic injections of epinephrin, the result being, apparently at least, prevention in increase of deafness. It was also hoped that this might prevent the evidence of otosclerosis in the child. I have already discussed this phase of the subject.¹

The last two epidemics of influenza demonstrated that severe mastoid and sinus complications induced miscarriages in pregnancies of more than three months' duration; however, if pneumonia was present before the miscarriage, the woman usually succumbed.

Another question of great importance is whether or not a nose or throat operation should be performed on a pregnant woman. I feel it best to postpone all operations under the circumstances except those that are urgent. These have not been followed by untoward results in my own experience.

9. *Ophthalmology*.—The cooperation between ophthalmology and otolaryngology has been long established, first, because it has long been the custom of many physicians to associate the two specialties in their practice, and secondly, because the pathologic relation of the nose to the eye has been recognized for many years. During the last two decades, the dependence of many eye affections on the paranasal sinuses has been the subject of much study. While this was formerly fairly limited to the suppurative processes, it has now been extended to include the nonsuppurative conditions which, indeed, have been found of more prolific etiology in this respect than the former. Keratoconjunctivitis, iritis and uveitis are commonly found to be due to focal infections of the tonsils, sinuses, middle ear, mastoid and teeth.

Nystagmus is a symptom that pertains to both the eye and the ear, which makes it necessary to determine the origin. Paralysis of the various extrinsic muscles of the eye may be due and often is due to sinus or temporal bone infections. Likewise muscle imbalance may be due to sinus disease, and it is not uncommon to see a refractive error or latent hyperopia disappear only when the nasal or sinus trouble has been corrected.

10. *Genito-Urinary Diseases*.—Nephritis needs only to be mentioned. As we have considered it under the head of internal medicine, the genito-urinary system need be discussed only from the standpoint of the pelvis of the kidney, bladder and prostate gland. These may be the seat of a chronic septic infection, independent or secondary to a focus of infection in the upper respiratory tract. Some very striking results have been reported from attention to the prostate without treating the tonsil. In my own practice I have had a case of chronic cystitis of long duration promptly recover after tonsillectomy.

11. *Clinical Laboratory*.—This term I use to include radiology, serology, hematology, bacteriology, chemistry and micropathology. The man in charge of such a laboratory should be a physician, preferably an internist, and he should have a corps of technicians, at least two. The relation between the clinical labora-

tory and otolaryngology has really gone beyond the stage of cooperation, for practically every field of medicine has become dependent on the clinical laboratory for the basic understanding of diagnostic and therapeutic problems.

12. *Dentistry*.—Although dentistry has been a highly specialized branch of medicine which had what it arrogated to itself, the dignity of a profession in itself, it is fast becoming more and more attached to medicine. The mechanical requirements and accomplishments of the last fifty years carried it far away from its parent, medicine, and American dentistry has become famous by reason of the crown and bridge work, porcelain inlays and the like. It appears to be the function of dentistry to preserve the decayed teeth, stumps of roots, etc., and to supply their deficiencies by mechanical subterfuge. A great change, however, has come over the profession, as witnessed by the zealotry with which chronic apical infections are studied and the conspicuously energetic effort which is being manifested to remove every tooth or root which shows any evidence of being the seat of a focal infection.

All this has brought the dentist closer to the otolaryngologist, as these two must decide in the majority of cases just where the focal infection originates. The maxillary sinus has already furnished many points of contact, and it must remain a constant source of study for both from the etiologic and therapeutic standpoints. Impacted and infected wisdom teeth may cause a tonsillitis, generally unilateral, and their influence in peritonsillar abscess is now being made the subject of much study. Tinnitus and even reduction of hearing may depend on infected molars, removal of which causes the symptoms to subside. Orthodontia, which has accomplished much with and without the cooperation of the otolaryngologist, has still to answer a serious question. So far it has been available almost exclusively by the well-to-do. The poor have little chance to profit by its wonderful development.

CONCLUSION

While I advocate that every otolaryngologist should be well informed on all the other special branches of medicine in order to cooperate in diagnosis and treatment, it is only in the capacity of cooperator that he should consider his services and not supplant any other specialist.

2551 North Clark Street.

Industrial Sickness Statistics.—In the past not much attention has been given to the need for facts concerning the sickness problems of industrial establishments. Cases of illness have to some extent been recorded, but not in such a way as to permit analysis with respect to sex, age, occupation and other important conditions of physical status and environment of the persons concerned. It may appear to some that sickness records are unnecessary for plants having sanitary work places and no injurious processes or occupational hazards. Such an attitude is unjustifiable without knowledge of the sickness rates prevailing in these establishments. Under excellent conditions of work it is still possible for the frequency and severity rates of illness to be above the normal expectancy as the result of bad housing or other wrong living conditions, in which instance it becomes the duty of the employer to extend his activities beyond the confines of his factory or mine or store and to cooperate with municipal authorities and civic associations to right the injurious conditions responsible for the excessive disability discovered.—*Pub. Health Rep.*, April 9, 1920.

SOME FALLACIES REGARDING NARCOTIC
DRUG ADDICTION

S. DANA HUBBARD, M.D.

NEW YORK

In plumbing the depths of narcotic drug addiction one must travel an uncharted course, with guides and landmarks very uncertain and at best most unreliable; but when these are aided and abetted by the unscrupulous and unworthy, as well as the financially interested, all must appreciate that the situation is made more complex and the solution of the problem rendered more difficult, if not actually impossible. Add to this opinions giving color to pathologic processes that do not exist, and confusion worse confounded must occur.

Drug addiction today is a public health problem, as it is a menace to the health, welfare and comfort of the public. The extent of drug addiction is problematic, but it may be indirectly inferred when one estimates the amount of opium and cocain consumed annually in this country.

How much of these narcotics would be ordinarily used by physicians or hospitals in a year? Surely not anywhere near the amount credited as imported annually. Then what becomes of this vast amount of these drugs? It is, of course, used by persons as a "tippling" habit.

CLASSIFICATION OF DRUG USERS

The habitual users of narcotic drugs may be divided into two general classes: (1) Those who suffer from a disease or ailment requiring the use of narcotic drugs, and (2) addicts—dope fiends—drug habitués: those who use narcotic drugs for the comfort these afford and solely by reason of an acquired habit. The Harrison Narcotic law (U. S. Supreme Court, Doremus and Webb cases) says that drugs may not be given to keep the users comfortable by maintaining their customary use.

Class 2 may be divided further:

- (a) Correctional (underworld type).
- (b) Mentally defective (the constitutionally inferior person or the individual with feeble-mindedness).
- (c) Social misfits (the person whose maladjustment does not permit him to conform to social customs).
- (d) Fortuitous (the individual who has had an adequate reason for taking narcotics, but the reason has disappeared and the drug habit is continued because of the physical suffering which unaided deprivation brings).

Many addicts loathe their habit, but physically cannot break from it unaided. A number of addicts, especially those in class subdivision *a*, use the practice of drug indulgence in their jobs. In our experience in drug addiction in New York City we found that those in subdivisions *a* and *b* were mostly heroinists, while the morphinists were in *c* and *d*. The heroinist and morphinist have been thus differentiated by an outspoken physician: The morphinist has guts, while the heroinist has only bowels.

Bad associates and evil environments are the chief causes producing addiction among youthful habitués in this city. Of 7,464 cases observed from April 10, 1919, to Jan. 15, 1920, in the department of health clinic, 3.5 per cent. were morphinists, while 96.5 per cent were heroinists.

MAGNITUDE OF THE DRUG TRAFFIC

How much opium and coca are used annually in this country?

The magnitude of this traffic is indicated by these statistical facts:

For the fiscal year ended June 30, 1918, there were 233,491 registrants as required by the Harrison act. These included: physicians, 125,905; wholesale dealers, 831; dentists, 42,240; manufacturers, 888; veterinarians, 10,399; importers, 76; hospitals, etc., 3,799; educational, 138; retail dealers, 48,196 and miscellaneous, 258.

The average yearly consumption for the period 1910-1915 was 491,043 pounds, which at the price of \$40 a pound for opium would make a total value of \$18,841,720. The average consumption of coca leaves for the same period was 1,048,250 pounds. At the present retail price of \$1 a pound this would represent approximately \$20,000,000.

Illegitimate traffic is known to have increased enormously in recent years, and is a serious menace at the present time. It is through this channel that most of the addicts receive their supplies of narcotic drugs. It has been estimated that about 90 per cent. of the amount of opium and cocain entered for consumption is used for other than medical purposes. This may perhaps be an extreme view; yet when the consumption of opium in the United States is compared with that in other countries, we find that the per capita consumption here is from thirteen to seventy-two times as great as in other countries.

CONSUMPTION OF OPIUM IN VARIOUS COUNTRIES

Country	Consumption per Capita, Grains
Austria	1/2
Italy	1
Germany	2
Portugal	2 1/2
France	3
Holland	3 1/2
United States	36

The amount of cocain which can be produced from the leaves imported is approximately 150,000 ounces—sufficient for two and one-half doses for every person in the country.

It is estimated that one fourth is used legitimately; 112,500 ounces of cocain are therefore used illicitly.

When this magnitude is considered carefully and scientifically, and it is known what a demoralizing, debasing effect such practice has, is it not a very serious matter to know that 80 per cent. of the addicts visiting the department of health clinic are young men and women just out of their teens?

The importance of securing more accurate information, particularly statistical, of the extent and growth of traffic in narcotic drugs in the different localities, especially in the large cities, is coming to be more keenly appreciated by all authorities, and in the near future it is hoped that the medical and pharmaceutical professions will be able to furnish data bearing directly on this subject in order to aid both the legal and the public health officials.

METHODS OF CONTROL

The control of the narcotic menace, to be effective, will necessarily not only have to correlate the professions directly interested but also secure the cooperation of all charitable and social agencies in order to work out a program for the effective administration of antinarcotic laws, as well as the rebuilding of those unfortunate persons afflicted with the drug habit.

Our men and women in the shops, factories, offices and homes must be properly protected from this growing evil, and all individuals and organizations should concern themselves regarding the unsatisfactory con-

ditions prevailing, and aid in better enforcement of the statutes regarding narcotic drug addiction.

One of the very first needs is to make compulsory the reporting by physicians and others of addicts (Class 2) in order that these persons may be known and given careful and suitable consideration. Another regulation is that all prescriptions issued for opiates and cocain should be in duplicate, one for the druggist and the other for some central agency (preferably a local department of health), that the practice in this particular may be independently checked and controlled.

CHARACTERISTICS OF ADDICTS

The etiology of narcotic drug addiction is not unusual or complicated. It is a natural sequence of indulgence in narcotics for a more or less variable period. The very susceptible acquire the habit in very short periods of time, some as short as ten days (some girls state that, after having sniffed three or four times, the withdrawal symptoms were marked); but usually it requires a number of such indulgences. Medically considered, it is thought that any one taking repeatedly a drug for a period of from three to five weeks is in grave danger of becoming an addict. When addiction has been established, it is usually impossible for the individual to discontinue the use of the drug without outside assistance.

In the clinic, 7,464 cases were cared for; and while gradual reduction (one-half grain every other day) was the custom, yet it was extremely difficult to hold our patients to schedule. A number openly opposed reduction; and when the amount was cut down about half, they left the clinic, not to return, or to return under a different name to commence again at the maximum dosage (15 grains) and pursue another course of reduction. Many were detected doubling in this manner. Of the total mentioned above, less than 2,000 availed themselves of hospital aid, 23 per cent. being the actual admissions. This demonstrates that they either feared to undertake a cure or else did not want to be cured.

There is no conclusion to be drawn regarding susceptibility as concerns age, sex or marital conditions. The same statement might also be made regarding race, occupation and other similar factors. The chief direct cause appeared to be evil association, in our experience 96.5 per cent. giving this as the cause of the practice.

Addicts have been found engaged in all lines of work. An early analysis disclosed that the skilled and the unskilled were about evenly divided, and this continued in the final analysis to be a fact. It was astonishing to find that 23 per cent. were engaged in transportation; chauffeurs, trainmen, drivers and motormen being the chief occupations given by the patients themselves. The preponderance was in the order given. This fact is considered, especially in New York City, to be a grave menace. In a case recently tried (*U. S. Government v. Jacobs-Cardoza*), it was testified by a physician that the chauffeur needed cocain to keep him on his job, or else he would be inattentive and sluggish and be unable to take care of his car in an emergency.

In a study of the occupations as a determining factor in causation, it was demonstrated that when hours were irregular, meals badly served, and stress and irritations frequent, addiction was more common. It was most frequent in those who handled the drugs, physicians,

nurses and pharmacists being proportionately the largest indulgers.

The effect of addiction on the character of a person was marked. Some drug addicts appear perfectly normal even to the experienced observer. Some were determined to be addicts with considerable difficulty. In the weak willed and those lacking character and where a drug-jag was apparent, determination was easily made.

The addict is not always a hopeless liar or a moral wreck or a creature sunk in vice and lost to all sense of decency and honor, but was frequently in our experience an upright person except as concerned his affliction or the procuring of the drug of his addiction. Addicts lied about dosage; but when they found that the game was "on the level" they would voluntarily admit deception and tell what they were actually taking.

When it is considered how these creatures were hounded and imposed on by the illicit prescriber and dispenser, as well as how they endeavored to escape police detection and family discovery, it was natural to meet some peculiar situations; but when sanctuary was assured, they calmed down and became friendly and communicative, and in many instances helped the officials to aid them in getting rid of their habit. Most of them when freed are anxious to remain free. I have been assured of this so often by addicts who have been off the drug and whom I have followed up that I make this statement advisedly and with positive assurances that many of our cases are off the drug for good, provided all temptation is removed. There were many instances in our experience in which the victims of this condition were persons of the highest qualities, physically, morally and intellectually, and some held high positions of authority and responsibility. One is a signalman who for twenty-five years has been addicted, yet has not missed a day from work and has never been reported for any company infraction, and, strange to relate, his superior officer was wholly unaware of his misfortune. This man took the cure and returned to his position, and for the last six months has been off the drug.

The correctional class I do not desire to discuss here, as the subject is one which merits special and lengthy consideration. The underworld addict is grossly misunderstood. While drug indulgence has been held accountable for his unmoral character, those whom I have had opportunity to study show degeneracy incident to association and environment, and addiction only as a secondary expedient for stimulating nerve energy and drowning painful reminiscences.

PROGNOSIS AND TREATMENT

The prognosis of narcotic drug addiction depends primarily on two conditions: control of the drug and control of the addict.

Simple, uncomplicated drug addiction is curable. By this I mean that the process of removing the drug and all physical need or craving for it is simple, safe, and can be quickly done—a matter of days only, not weeks, months or years, as some would have us believe.

There is no specific cure; none is needed. Take away the drug and prevent the addict from getting a new supply, and not only will he be cured but he will stay cured.

Addiction is not a mysterious disease, and while, from a purely scientific point of view, it would be

interesting to have more light on the problem of tolerance, there is a very general and complete understanding of drug addiction from the therapeutic standpoint among all who have dealt with it in institutions.

In the vast majority of instances—99 per cent.—excellent results may be obtained by simple abrupt withdrawal, without medication other than catharsis. Some form of mild anesthetic to tide over the first two or three days of suffering, which is mainly psychic in origin, is desirable from a humane point of view. Scopolamin (hyoscin) is ordinarily used for that purpose, but it is stated that belladonna works equally as well.

The clinic has proved in a large number of instances that it is so seldom that one can cure by the method of ambulatory treatment—that treatment in which the drug is given to the patient for self-administration—as practically to stamp such practice as improper. The method should not be permitted. It should be interdicted by law.

CONCLUSIONS

So long as addicts can obtain cheap supplies of drugs without personal risk, very few will apply for hospital curative treatment.

Narcotic drug addiction can be stopped by sufficiently stringent laws, strictly and uniformly enforced.

Public narcotic dispensaries are not desirable or satisfactory in dealing with the problem of drug addiction. This method has been given a careful, thorough and extensive trial in New York City, and we have come to the conclusion that it is unwise to maintain such an institution. The clinic was found to possess all the objectionable features and opportunities of abuse presented by the ambulatory treatment of private physicians prescribing to the addict when at large, except one factor, namely, financial profit to a few physicians performing this character of service (fifty-five out of 8,100 registered in New York City).

Ample provision should be made for hospital or institutional treatment to cover the stage of withdrawal and for the control, care, and moral and mental as well as physical upbuilding of those persons who require it and show the possibility of profiting from such treatment.

Our study and experience indicate very clearly the necessity for general and uniform enforcement of the law—the Harrison Narcotic Law. There will be no panic of addicts seeking medical relief. Prevent the addict from getting his drug, and in very many instances he will cure himself, and if unable to get the drug he will stay cured. Some have stated time and again that rapid withdrawal will be followed by collapse. It is always well to treat all cases under medical supervision, and physicians experienced in this line of medical practice know that a very small dose of the drug (from one-fourth to one-half grain hypodermically) will control all manifestations of withdrawal.

The work of reclaiming narcotic addicts is well worth while. From our recent experience I assert without fear of contradiction that at least of the many undesirables no less than one half can be brought back to useful lives, and that one fourth should be, in some special institution (the types classified in *a* and *b*) where, with suitable care and training, many can be made useful citizens instead of merely being impedimenta and parasitic.

Off the drug, and with life made comfortable by suitable guidance the addict, like every normal person,

faces his daily problems and can do so; but to stand alone requires after-care until he can feel at home in his new surroundings. This may take several months; but with help, redemption is sure.

The problem of narcotic drug addiction may be summed up in the problems of life, the underlying causes being more personal than social. Treatment is likewise individual and not specific.

The drug addict serves no useful purpose. He is a loss to himself and a menace to society. Addiction begins and ends in the realm of personality.

ANTHRAX: COMPARISON OF SURGICAL AND NONSURGICAL METHODS OF TREATMENT

A REVIEW OF FIFTY-ONE CASES TREATED AT THE
MASSACHUSETTS GENERAL HOSPITAL FROM
1888 TO 1918

ALBERT J. SCHOLL, JR., M.D.
LOS ANGELES

Historically, the anthrax bacillus is of much interest. Pasteur's trials and triumphs in anthrax inoculation and immunization are well known. Davaine, working with this bacillus in 1863, and later Koch, opened up a new era in bacteriology when for the first time a micro-organism was definitely proved to have a specific etiologic relation to an infectious disease.

Anthrax is a specific and highly contagious disease, common to man and to most animals, and, according to Osler, geographically and zoologically the most widespread of all the infectious diseases. It is quite prevalent in France, Italy, Russia, China and South America, although in North America cases are rather infrequent, so much so that the occasional small epidemics find physicians undecided as to the course of treatment. Anthrax in man is always derived from some domestic animal or animal product, such as hide, hair or wool. The lesion appears about twenty-four hours after inoculation, and in the early stage resembles an ordinary small furuncle; but very quickly the central portion becomes filled with a bloody serous material. This rapidly changes to a black central necrosis which, on drying, gives the typical small, black eschar, or crust, commonly seen at the time patients come for treatment. This eschar is encircled by a ring of small, pearly vesicles, and surrounding this is a rather extensive brawny edema.

In animals the disease is contracted by the ingestion of forage containing anthrax spores. Flies evidently also play a minor part, as Schuberg¹ succeeded in transferring the infection from a cadaver to living animals by means of the stable fly. He also demonstrated that anthrax organisms remained viable in the stomach of flies for months, while Graham-Smith¹ recovered positive cultures from feces of house flies three years after deposition. The bacillus itself is easily destroyed; but in the presence of oxygen, markedly resistant spores are formed which are not affected by ordinary means of disinfection.

REVIEW OF CASES

The cases of anthrax treated at the Massachusetts General Hospital between 1888 and 1918 are the basis

1. Cited by Mitzman, M. B.: Summary of Experiments in the Transmission of Anthrax by Biting Flies, *Bull. 94, Hyg. Lab. U. S. P. H. S.*, pp. 41-48.

of this study. The interesting contrast of results between the surgical and nonsurgical methods of treatment affords sufficient excuse to add this series to an already overburdened literature. In recent articles on anthrax, surgery and cauterization are frequently advised, but statistical reports are strikingly few.

These cases were not selected as surgical or nonsurgical, according to the condition of the patient. The nonsurgical cases are more recent and were treated conservatively following a suggestion by Dr. J. Homer Wright.

COMPARATIVE RESULTS OBTAINED IN CASES TREATED
SURGICALLY AND NONSURGICALLY

	No.	Per Cent.
Total cases	51	
Total deaths	7	13.7
Cases treated surgically	9	
Deaths	4	44
Cases treated nonsurgically	42	
Deaths	3	7

The average duration of the disease in patients that recovered was twenty-three days. Death in the seven fatal cases occurred on an average of four days after the onset of the disease.

In forty-two, or 82.3 per cent., of the cases, the lesion was located on the face or neck. Infections in this region are considered especially dangerous on account of the proximity of vital structures. The loose cellular tissues in this area aid in the spread and extension of the local lesion, and the resulting edema in the neck often gives rise to marked respiratory difficulty.

Thirty-eight infections were in men engaged in handling hides; of these, twenty-three were leather tanners. All of the patients treated were males except one. This was a girl, aged 17, who was employed sorting bristles in a brush factory.

The general symptoms found in this disease, such as nausea and vomiting, restlessness and headache, are often absent and have no constant relation to the extent of the disease. In the majority of cases a rise in temperature of 2 or 3 degrees was noted which generally persisted only for from three to four days. Cases which are ushered in with marked symptoms and a sharp rise in temperature indicate a definite reaction on the part of the patient, and in such cases there was a favorable and rapid termination of the disease. The temperature is often low in grave cases, and in several a subnormal temperature was noticed just before death.

Anthrax is often mistaken for cellulitis or a carbuncle. An early diagnosis of the condition can be made bacteriologically by demonstration of the anthrax bacillus in the lesion. After the crusting over of the lesion, it is necessary to elevate the cutaneous edge and probe between the crust and the skin in order to find suitable material for examination. Of the fifty-one cases of this series, the anthrax bacillus was found in forty-one; in two cases negative results were reported, and in nine no record of the presence of the bacillus was made.

The patients were isolated, and precautions were taken against the spread of the infection. In the majority of cases, there was no discharge, and no case of reinfection was noted. The anthrax bacillus does not form pus. In one case, fifteen days after the onset of the disease, the initial lesion having practically healed, definite swelling and brawny induration indi-

cated pus in the region of the submaxillary gland. Wide excision of this area with a thorough spreading of the tissues failed to reveal any pus.

The first of the four deaths in the Massachusetts General Hospital following surgical procedure in the treatment of anthrax occurred in a man with a lesion of the right cheek. The patient died nine hours after excision of the pustule without having rallied from the operation. In the second case of death, a spreading of the edema was noted directly after operation, which consisted in a wide excision of a lesion in the neck. Seven hours later the patient was pulseless, the temperature dropped to 97 F., and death occurred shortly after. The third death was also in a case of anthrax of the neck; an elliptic incision 10 by 12 cm. was made down to the deep fascia. This patient showed some improvement; but on the second day after operation, the edema extended, and the patient died on the following day. The fourth death was in the case of a lesion on the arm; a crucial incision was made, but rapid extension of edema followed the operation, and the patient died several days later.

A fifth patient with an infection on the forearm recovered after an amputation at the shoulder joint. The remaining four of the group of nine patients treated surgically had uneventful convalescences following the excision of the lesion.

Patients treated nonsurgically were confined to bed. Whenever the location of the lesion permitted, the infected area was splinted and elevated. A light diet was given, and fluids were forced to the maximum amount.

The infected area in the earlier cases was covered with dry gauze or mercuric chlorid poultices. The cases treated during the last three years cleared up more rapidly, and the patients were more comfortable when no dressings were used, the lesion being exposed to the air.

Anthrax patients were considered potential sources of infection until three consecutive smears taken on alternate days proved them to be otherwise.

Of the three deaths in the nonsurgical cases, the first occurred in a patient with a lesion on the right side of the neck. Edema extended over the face, neck and upper chest wall. The blood gave a positive culture for anthrax. The patient was markedly dyspneic and had practically stopped breathing when a hurried tracheotomy was performed without benefit. The second death also occurred in a case of cervically located lesion. There was marked edema and respiratory difficulty. A tracheotomy was performed through infected tissues without noticeable relief to the obstructed breathing, and the patient died two hours later. The third patient who died among those treated nonsurgically entered the hospital three days after the onset of a lesion of the right cheek. Edema was moderate, and the patient was not considered dangerously ill. On the afternoon of the first day in the hospital, the patient suddenly sat up in bed, complained of a pain in his chest, and died.

The immediate cause of death in anthrax infections is not definitely known. The decidedly toxemic nature of the disease in man indicates the existence of poisons, even though true secretory or endotoxins have not been isolated. Vaughan in summing up the results of his experimental work on anthrax, states that the pathogenicity of a bacterium is not measured by its capability of furnishing a poisonous group, but by its

ability to grow and multiply in the animal body. Hiss and Zinsser state that it is probable that death is brought about by purely mechanical means, such as capillary obstruction.

METHODS OF TREATMENT

Ravenel¹ states that anthrax begins as a local infection, and that the bacilli are localized in and near the lesion. For this reason, he advises immediate destruction of the pustule or focus of infection. Most surgical textbooks advise radical removal as the safest recourse.

Hiss and Zinsser assert that although the bacilli are not demonstrable in the blood until just before death, they invade the blood and lymph streams immediately after inoculation and are conveyed to all the organs. This was demonstrated by inoculations in the tails or ears of guinea-pigs, after which these parts were immediately amputated. The spread of the disease and fatal outcome were not prevented by these measures. The bacilli in the early stages are not able to multiply in the blood, however, at the site of inoculation, and probably in the organs also, they proliferate until the resistance is entirely overcome. At this stage of the disease, when the antagonistic action of the blood has been destroyed, the bacilli may multiply in the circulation and can then be demonstrated in the blood. A positive blood culture was found in only one case of this series.

Becker² made a study of blood cultures in forty-one cases. Eleven of the cultures were positive; ten of the patients died. The eleventh was treated intravenously with arsphenamin and recovered. Roos³ asserts that in animal experimentation he found arsphenamin to have a specific action on the anthrax bacillus, acting directly on the bacteria. Laubenheimer⁴ also reports a case with positive blood culture successfully treated with arsphenamin.

Prätorius,⁵ whose experience with anthrax has been very extensive, advises against surgical interference, as this opens up the lymphatics and aids in the spread of the disease.

Müller⁶ asserts that it is impossible to destroy the disease by excision of the site of inoculation. He carried out a series of experiments similar to those cited by Hiss and Zinsser. In guinea-pigs, he was unable to prevent the spread of the disease by amputation of the inoculated area. He states that treatment should aim to assist the cells about the inoculated area in preventing dissemination of the bacteria. Excision is harmful, as it tends to break down the natural barriers to the local infection and to increase the absorption of the toxic substances around the lesion. In a number of cases in the Massachusetts General Hospital series, operation was so closely followed by extension of the edema, septicemia and death that it was undoubtedly a causative factor. Müller believes in immobilization and elevation of the infected part; he reports thirteen successfully treated cases. Eurich⁷

asserts with regard to immobilization that the most severe cases are those in which the lesion occurs in parts of the body in which motion is free and in which the cell tissues are lax. Three of his ten patients who had lesions on the wrist died. There were no deaths among the ten patients with infections on the arm. Eurich insists that absolute rest of the part affected is necessary.

Graef⁸ reports 384 cases in which cauterization with potassium hydroxid was performed with only a 5 per cent. mortality. Potassium hydroxid is extremely painful when applied to the skin, and often leaves extensive scarring. Pied⁹ drives a blast of hot air on the lesion through a small needle, until the eschar and vesicular area are completely cauterized. He asserts that no anesthetic is necessary, as there is an anesthesia to pain and heat about all anthrax lesions. He advises continuing the cauterization 0.5 cm. beyond the anesthetic area.

Muskett¹⁰ found in laboratory experiments that ipecac readily destroyed the anthrax bacillus. He cites fifty cases successfully treated by applying powdered ipecac to the lesion. Fortineau¹¹ found an antagonistic action between *Bacillus pyocyaneus* and *Bacillus anthrax*. He treated thirty-two patients by injection of an extract from a culture of *Bacillus pyocyaneus*; one patient died.

A number of recent articles on anthrax mention phenol (carbolic acid) injection. Scharnowski⁸ reports fifty cases from Russia, with a 2 per cent. mortality. Regan¹² reports a successful case, and suggests phenol injection at the site of the wound.

Anthrax serum was used in only one of the cases of this series. The temperature, which had remained at 103 F. for five days, dropped immediately after the first injection and remained normal. Sclavo, in 1895, in Italy, and Marchoux, in 1895, in France, reported the use of anthrax serum. The serum has been used extensively in Italy and also recently in France, but only rarely in this country, although it is readily obtainable here. Legge¹³ studied a series of cases in Italians treated by Sclavo with serum. In 164 cases there was a mortality of only 6.09 per cent., in contrast to 24 per cent., the rate for all cases treated in Italy over a period of fifteen years.

Pied⁹ cites nine cases with a positive blood culture, in seven of which serum treatment was used successfully. Bissell¹⁴ and Graham¹⁵ also report two cases with positive blood culture, successfully treated, serum having been used.

Bowlby and Andrews¹⁶ report a case in which cultures from the vesicles around the lesion yielded abundant anthrax bacilli. Nineteen hours after an injection of serum, cultures similarly taken were negative. Serum, which is evidently not harmful to the patient, generally arrests the extension of the edema,

which is the most troublesome feature of the disease. Krause,¹⁷ in a number of recent articles, reports successful results from the use of normal serum in the treatment of anthrax in man. From 30 to 50 c.c. are injected daily, either subcutaneously or intravenously until the acute symptoms have subsided. Two hundred cases are reported with a 0.5 per cent. mortality. Kolmer,¹⁸ after experimenting with beef serum, concluded that while it contained some antibactericidal properties, they were without demonstrable protective and curative value in experimental anthrax infections in mice and rabbits.

COMMENT

The majority of the methods of treating anthrax described in the literature are conservative. Surgical intervention offers very little. The organism is building up protective barriers and walling off and splinting the infected area. The main contention of those advising surgery is that the lesion is strictly a local one, and excision should be performed before generalization takes place. On the contrary, there is probably a systemic infection from the onset, but in most cases it is not so great that the organism cannot overcome it. The involvement of neighboring lymph glands which is seen in most cases, and the marked edema which, at times, extends as much as 25 cm. beyond the local lesion, argue against a localization of the infection. A wide excision through this edematous area, giving an extensive field for absorption, opening up many new portals of entry is sufficient, in some cases, to overcome completely the resistance of the patient.

SUMMARY

1. The early diagnosis is made bacteriologically by the demonstration of the anthrax bacilli in the wound. Anthrax bacilli were found in 81.2 per cent. of the cases treated at the Massachusetts General Hospital.
2. The general symptoms give no constant indication of the severity of the infection.
3. The mortality in the cases reviewed was 13.7 per cent.
4. Four of nine patients (44 per cent.) treated surgically died; only three (7 per cent.) treated nonsurgically died.
5. Forty-two patients had lesions on the face and neck. Cervical infections are especially dangerous; two of the patients treated nonsurgically died from respiratory difficulty resulting from the associated edema.
6. The patients treated nonsurgically were confined to bed. Their lesions were left absolutely alone and exposed to the air; no special general measures were carried out.
7. In several of the surgical cases a rapid increase in the edema, a steady decline in the patient's general condition, and death several hours later definitely pointed to the operation as the causative factor.

Disease and Symptoms.—Disease is made manifest to us only by the symptoms it produces, hence it is imperative that the first step should be to understand the nature and significance of symptoms.—J. MacKenzie, *Brit. M. J.* **1**: 105 (Jan. 24) 1920.

SUCCESSFUL TREATMENT OF GIARDIASIS IN MAN WITH NEO-ARSPHENAMIN

E. I. CARR, M.D.

LANSING, MICH.

AND

W. L. CHANDLER, Ph.D.

Research Associate in Entomology, Michigan Agricultural Experiment Station

EAST LANSING, MICH.

The pathogenicity of *Giardia (Lambli) intestinalis* is now fairly definitely established; in fact, this flagellate has recently been described as the causative organism of "trench diarrhea,"¹ a dysenteric condition which most of the overseas troops experienced and from which a number of the returned soldiers are still suffering.

Several different medicaments have recently been employed in the treatment of this disease; and, while some of these² have been found to give temporary relief, no permanent cure has hitherto been effected.

The rôle which salts of heavy metals, notably mercurial and arsenical preparations, play in the treatment of syphilis and some other flagellate diseases is common knowledge; and at least two groups of workers have observed that the cysts of *Giardia muris* disappeared from the feces of infected rats following intravenous injections of heavy doses of arsphenamin. Probably the most noteworthy of these observations are those made by Kofoed and his associates.¹ However, so far as we are aware, no attempt has been made to utilize these substances in the treatment of human diseases caused by intestinal protozoa.

Since neo-arsphenamin is being used with good success against the syphilis flagellate, it occurred to us that intestinal flagellates, and possibly also other intestinal protozoa, might prove to be susceptible to the action of this product; and, moreover, since the oxidation products of neo-arsphenamin are readily excreted by the way of the intestinal tract, intestinal protozoa ought to be more easily reached than the syphilis organism, which is often intracellular. It was, therefore, not surprising when in the course of our investigations we observed that not only the cysts of *Giardia intestinalis* and *Chilomastix mesnili*, but also those of *Endamoeba coli*, *E. histolytica* and *E. nana*, rapidly disappeared from the stools of man following intravenous injections of neo-arsphenamin, and that the cysts of *Eimeria stiedae* disappeared from the feces of rabbits following intramuscular injections of heavy doses of neo-arsphenamin. Whether or not the results obtained through this treatment are permanent is yet to be determined. A number of cases are under observation, and these will be reported on as soon as a sufficient period of time has elapsed to enable one to draw definite conclusions. In the case here reported, however, a permanent cure appears to have been established.

REPORT OF CASE

History.—W. G. S., aged 25, American, a salesman, formerly a soldier, who came in July, 1919, complained of

1. Kofoed, C. A.; Boeck, W. C.; Minnich, D. E., and Rogers, J. H.: On the Treatment of Giardiasis in Rats with Arsenobenzol, *J. Med. Res.* **39**: 293-299 (Jan.) 1919.

2. Wenyon, C. M., and O'Connor, F. W.: Human Intestinal Protozoa in the Near East, published for the Wellcome Bureau of Scientific Research by John Bale, Sons & Danielsson, London; reprinted from *J. R. A. M. C.* **28**: 1-34, 157-187, 346-370, 461-492.

abdominal pain more or less continuous but varying in intensity and interfering greatly with work, together with an intermittent diarrhea. The family history was negative. The personal history was negative as regards the present trouble. June 22, 1918, the patient entered the army. He was detailed to a northern university for study, and on Oct. 16, 1918, he was sent across. He remained in Brest nine days. On the ninth day a distressing diarrhea started, and persisted all night. This was the only serious acute attack that he had, but he continued to have from four to six movements a day for the remaining six months he was abroad. Part of this time the stools were black. He received no treatment. He was discharged, March 11, 1919. The patient experienced a return of abdominal distress in May or June, 1919, when it gradually became worse. He lost twenty-five pounds in four months. Frequent stools varied with the pain, and were watery, containing much mucus and some blood. He had been examined several times and had been variously advised. In one hospital he understood the diagnosis to be duodenal ulcer, and it was with this belief that he came to us for advice and treatment.

Examination.—Conclusions were drawn from physical and roentgen-ray examinations that a gastric or duodenal lesion did not exist and that the irritable intestinal tract must result from a parasitic or reflex cause. The Wassermann test was negative. The urine had a specific gravity of 1.025; it was neutral and clear; Fehling's test was negative; there was a trace of albumin; the sediment was negative. Macroscopically, the stool was unformed, dark brown, almost black, and pasty; it contained some mucus; the patient reported a bloody mucous stool a few days previous to this examination. On microscopic examination a few motile forms of *Endamoeba histolytica* and numerous cysts of *Giardia intestinalis* of the so-called "large race" were found.

TREATMENT

Emetin.—On establishment of the diagnosis of amebic dysentery by the identification of *Endamoeba histolytica*, one-half grain of emetin hydrochlorid was administered hypodermically daily, together with two alcresta ipecac (Eli Lilly Company) tablets by mouth three times a day after meals for fourteen days. Stool examinations were made daily.

Results: *Endamoeba histolytica* disappeared from the stools on the second day and did not reappear. No cysts of this organism were encountered. The character of the stools improved; they were less frequent, less watery, and contained less mucus and no blood that could be detected macroscopically. There was no appreciable decrease in the number of cysts of *Giardia intestinalis*. The abdominal discomforts still persisted.

Sulphur.—In September the patient's stools again became frequent and semifluid. The endamebas were absent from the stools, but the cysts of *Giardia intestinalis* were present in even greater numbers than before. A sulphur treatment was instituted in the hope of controlling this flagellate. Beginning with 15 grains and gradually increasing to 25 grains, sublimed sulphur was administered by mouth three times daily for fourteen days. Stool examinations were made every alternate day.

Results: On the second day the number of cysts was found to be greatly reduced; on the fourth day cysts were detected only after concentration of the stool by centrifugation; on the sixth day the number had greatly increased, while on the eighth day and thereafter the cysts were as abundant as ever. No change in the patient's condition was observed.

Neo-Arsphenamin Treatment (single injection).—In November the patient reported severe abdominal pains, and was able to obtain relief only by wearing a tightly fitting bandage over the point of attack. November 29, 0.6 gm. of neo-arsphenamin was introduced into the blood stream. Stool examinations were made daily for six successive days.

Results: Examination was made of the last part of a stool passed three hours after the treatment; no cysts were found at this examination; however, unfortunately, no examination

was made of the first part of the sample passed, nor had a stool examination been made for six days previous to the treatment. The cysts did not reappear in the stools during the six days following the treatment. The patient's condition improved and he was able to remove the bandage.

Neo-Arsphenamin Treatment (three injections).—December 24, the patient reported a recurrence of the abdominal discomfort. An examination of his stool made on this day revealed numerous cysts of *Giardia intestinalis*. These cysts varied greatly in size and shape; some typically shaped cysts were only one-third the usual size, others were larger than normal, while still others were flat on one end. December 24 and 29 and January 2, intravenous injections of 0.6 gm. each were made; and, following the second injection, calomel and castor oil were administered by mouth. Stool examinations were made daily for twelve successive days during and following the period of treatment; and for six successive days once a month thereafter.

Results: The cysts of *Giardia intestinalis* were greatly reduced in number in the first sample collected after the first injection and were entirely absent from the stools on the second day after the first injection, and have not since recurred. The patient's condition has greatly improved; his stools have become normal and his abdominal discomforts have abated.

INCIDENCE OF TUBERCULOSIS IN HUSBAND AND WIFE *

ARNOLD MINNIG, M.D.

DENVER

A great deal has been written on the degree of infectiousness of the tuberculous consort to the well one. The pendulum has swung from one extreme to the other. It is about time we were taking what I consider a sane view of the matter. The question is whether or not there is such a thing as adult infection. If there is such a thing we have in the man and wife the ideal relation, or culture medium, namely, prolonged and intimate contact.

Probably the most radical exponent against the theory of adult infection is Fishberg,¹ who says he has never observed a case of tuberculosis transmitted from one consort to the other. He gives as proof of the impossibility of adult reinfection the fact that the hospital staffs in institutions harboring tuberculosis patients do not suffer from tuberculosis more than others.

In another study, Fishberg² has investigated the conditions under which many of the tuberculous live. He examined 170 consumptives, nine of whom were women and 161 men. In the latter group he found that seventy-eight of the wives lived with their tuberculous husbands at home, and of these fifty-one slept in the same room and twenty-three even shared their beds with them. Of the rest, twenty-seven of the tuberculous husbands were inmates in sanatoriums or hospitals for consumptives, and five were away from home, though not in institutions. He also found that during the time of the illness of the affected consorts, forty-eight children were born. Out of this number Fishberg found that in only 3 per cent. of the cases both husband and wife were tuberculous—a rather strong argument against adult infection.

* From the Denver Municipal Tuberculosis Dispensary.

¹ Read before the Medical Society of the City and County of Denver, April 6, 1920.

2. Fishberg, Maurice: The Rarity of Conjugal Tuberculosis, Am. J. M. Sc. 153: 395 (March) 1917.

Sir Hermann Weber³ found in "sixty-eight persons, male and female, who with more or less pronounced consumptive taint had married healthy partners, that ten of the partners of these sixty-eight cases became consumptive, or 14.7 per cent. Nine of the tuberculous husbands lost eighteen wives, namely, one lost four, one lost three, four lost two each and three one each."

1. Burney Yeo⁴ collected records of 1,055 cases of consumption, which had come under his observation consecutively in the hospital. Of this number, 621 were males and 434 females. Of the males, 306 were married, 297 were single, and eighteen were widowers. Of the eighteen widowers, only two, or about 11 per cent., could state positively that they had lost their wives by consumption. Of the 434 females, 199 were married, 206 were single, and twenty-nine were widows, only five or 17 per cent., were able to state positively that their husbands had died of tuberculosis.

Among 159 couples in which one of the partners was tuberculous, Brehmer⁵ found that in nineteen, or 12 per cent., both suffered from the same disease.

Haupt⁶ found in 417 cases twenty-two, or 5.2 per cent., in which both partners were affected with tuberculosis.

Cornet⁷ found among 594 couples that both partners were tuberculous in 23 per cent. of the instances.

Jacob and Pannwitz,⁸ in a collective investigation in several German sanatoriums, found that in 8.57 per cent. of the cases, conjugal tuberculosis was present.

An excellent and exhaustive statistical work on this subject has been published by William Weinberg,⁹ who found that among 1,426 husbands of tuberculous wives, 118, or 8.3 per cent., died from this disease. Among 2,506 wives of tuberculous husbands, 112, or 4.5 per cent., succumbed to this disease, or among 3,932 consorts of tuberculous persons 230, or 5.9 per cent., died from tuberculosis. He thus finds that the mortality from phthisis among those who are married to consumptives is about double that observed in the general population, in which it is about 2.7 per cent.

Ludwig Levy¹⁰ investigated 317 married couples who lived in poverty and want. Thirty-four per cent. shared the same bed. Two and eight-tenths per cent. of the disease was due to marital infection.

Ward,¹¹ in an analysis of 156 cases in which the mate of a tuberculous husband or wife was examined, found the extraordinary number of ninety-one, or 58 per cent., tuberculous. Sixteen were considered suspicious, and forty-nine negative.

Wilson Fox¹² cites a few cases of great interest:

A. A phthisical man married several times, and most of his wives became phthisical.

B. A consumptive man died, having transmitted the disease to his wife, who infected her second husband.

C. A man infected his wife and died. His widow remarried and also died of tuberculosis, as did her second husband, after

he had remarried. His widow lived and also married again, and the next husband died of tuberculosis.

D. A woman married two tuberculous husbands in succession and became tuberculous after the death of the second.

E. A consumptive wife died leaving an infected husband, who infected a second wife.

F. A consumptive wife, before dying, infected her husband, who later infected a second wife. This widow afterward infected a second husband.

G. A woman died of tuberculosis. Her husband, not said to have been tuberculous, married three other wives. Of his four wives, the first, second and third died of tuberculosis, but the fourth wife and the husband were apparently free from the disease.

Another convincing study has been made by Crouch¹³ of the Modern Woodmen Sanatorium, Colorado Springs. His investigations covered 4,100 cases, all males. Of this number, 2,771 were married, and 233 were widowed. Out of this total of 3,004 cases, 193, or 6.4 per cent., had wives who showed either a history of tuberculosis or who had died of tuberculosis. In the consideration of the widowers, however, he found that 136, or 58.37 per cent., lost their wives from tuberculosis. He concludes that "58.37 per cent. of tuberculosis among 233 widowers is certainly more than a coincidence."

The conclusions of other men who have made a special study of marital tuberculosis with the percentage of contagiousness they have found in their investigations are given herewith: Elsasser,¹⁴ 39 per cent.; Gebser,¹⁵ 5 per cent.; Jousset,¹⁶ 3 per cent.; Thom,¹⁷ 3 per cent., and Turban,¹⁸ 6 per cent.

There is a variation in the statistics of from 3 to 58 per cent. Of course, it is possible that both husband and wife may have tuberculosis when they marry, which contingency has to be taken into consideration.

Levy¹⁰ and Ward¹¹ have made the interesting observation that when the consort died and the other consort had clinical tuberculosis, often the infection after six months was overcome or the patient was much improved. This occurred in spite of the fact that usually there was the added responsibility of taking care of the children alone. This was true not only in the case of the surviving husband but also in the case of the surviving wife. This would show that the continued massive infection was each day lowering the consort's resistance; but when he was not exposed to the continuous culture of tuberculosis, he improved.

RESULTS OF AUTHOR'S INVESTIGATION

In my investigation, which covered 1,000 successive dispensary cases, I was especially careful to classify none as tuberculous which were in the least doubtful.

I considered that a case was tuberculosis if the bacilli were present, or if there was a history of hemorrhages, a number of attacks of pleurisy, dulness with persistent moisture over the apexes continuing for a year or more, or if the patient died of tuberculosis. In other words, I considered only positive cases of tuberculosis and no suspects. In the series of cases, 502 of the patients were married and 498 were single.

I found that among these 502, there was active tuberculosis in husband and wife in forty-four cases, or 8.7 per cent. Of the forty-four cases, twenty-two of the consorts had died of tuberculosis, or 50 per

cent. Of the twenty-two surviving consorts, seventeen were men and five women. In these twenty-two, tubercle bacilli were present in twelve of the widows or widowers. The period of illness extended from four months to twenty years.

Of course, it is to be borne in mind that my investigation dealt only with the poorer classes. I have not included in the forty-four any cases in which, for instance, there was dulness with suppressed breath sounds or even bronchovesicular breathing at one or both apexes and a vague history of pleurisy or other mild symptoms, but no moisture. No doubt many of these were tuberculosis carriers, yet not clinically open cases of tuberculosis; but no doubt, they were open cases part of the time. Had I considered these, the percentage would be still higher.

That there are these carriers among us is shown by these private cases:

REPORT OF CASES

CASE 1.—A physician, aged 62, widower, weight 190 pounds, who had never been sick except that he had pneumonia at 25, who had been married twice to apparently healthy wives both of whom had died of tuberculosis, finally submitted himself to an examination. He was a well developed man. Over the left apex there was dulness and a few moist crackles after he coughed. There was no history of hemorrhage or expectoration. He suffered a severe attack of influenza in the recent epidemic, but made a good recovery.

CASE 2.—A widow, aged 28, had married at 19 a man who coughed and who had lost a sister of tuberculosis. He weighed 212 pounds at marriage, but lost 50 pounds in four months and died of tuberculosis two years before I saw her. The widow's family history was good. She had never been sick until her first baby was born in 1912 when, because she was catching colds often, she was advised to take what the physician termed a protective course of tuberculin. No doubt, she was having symptoms then. She had been coughing the past year and had lost 20 pounds. Six weeks ago, she was accepted by an old line life insurance company for \$10,000 ordinary life insurance. She did not expectorate except when she had a cold, but her sputum had never been examined at that time. She had persistent râles after cough; expiration was prolonged over both apexes, and the whispered voice was exaggerated over the same area. At the right base there was a definite pleuritic rub.

COMPARISON OF FINDINGS

My findings are in accord with those of most investigators. If we take the normal incidence to be 2.7 per cent. among all classes, we do not find anywhere in the literature so low a percentage in the consort of the infected husband or wife.

When I first entered dispensary work, I was rather prejudiced in favor of the theory of the nonexistence of conjugal or adult infection; but after working a number of years among this class of patients, I was impressed not by the rarity of tuberculosis in husband and wife, but by the fact that it was a rather common occurrence and as a result made the foregoing investigation, not of selected cases but of successive cases coming to the dispensary in the year 1918 and the early part of 1919.

CONCLUSIONS

1. I have found the incidence of marital tuberculosis to be 8.76 per cent. When a consort dies, the mate has been infected in 50 per cent. of cases.

2. There is such a thing as adult infection. We should constantly bear this in mind in our advice to the layman.

3. It is evident that when there is a continued massive infection over a period of years, and especially

when the consort dies, in these last years patients are especially careless and slovenly, and there is not only a possibility of contagion, but in one out of every two cases active tuberculosis supervenes.

4. My investigation covered only dispensary cases. In private practice the incidence of marital infection is smaller, proving that intelligent prophylaxis is worth while.

CALCULI IN THE SALIVARY DUCTS

REPORT OF FIVE CASES *

SEWARD ERDMAN, M.D.

NEW YORK

Calculi which form in the ducts of the salivary glands or in the glands themselves possess considerable clinical interest by reason of the peculiar train of symptoms, the infrequency of the lesion, and the necessity of a correct diagnosis. Unless the possibility of this condition is always borne in mind, and a careful diagnosis made, there will be numerous instances in which a totally unnecessary operation on the neck will be performed without relief of the symptoms. In one of the cases reported herewith, such a futile operation was performed despite the suggested diagnosis of calculus; and in two of the other cases, surgeons of equal or greater experience than myself were heartily in favor of a dissection of the submaxillary region for supposed lymphadenitis.

If this lesion is borne in mind, a careful history of the symptoms and a visual examination of the mouth of the duct, with a digital exploration of the floor of the mouth and buccal cavity, will in every case point strongly to the diagnosis. The roentgen-ray naturally suggests itself as the best method of diagnosis; but unfortunately it is not, and the results are very disappointing. In any event, the surgeon would first make the tentative diagnosis before a roentgenogram is made, and even its positive findings would only be corroborative evidence. As a matter of fact, the roentgen-ray report is all too often negative, when operation proves the presence of calculus. The explanation frequently given is that the calculus was lacking in material which would cast a shadow, but this is manifestly not so in any of our cases, as the accompanying illustrations show. The true explanation in most cases is that the technic of making pictures far back in the submaxillary and parotid regions is very far from perfect, and the reason that the roentgenogram is reported negative is that the lesion was never reached.

A technic intended to overcome the difficulties of the situation has been suggested by M. Arcelin.¹

Analyses of many different salivary calculi show that they contain both organic and inorganic matter; the nucleus is usually organic: organic matter, approximately 25 per cent.; calcium phosphate, approximately 60 to 65 per cent.; calcium carbonate, approximately 6 per cent.; with traces of iron, magnesium, etc.² They are usually oval or olive shaped if formed in the duct; but round or irregular if formed in the gland. The color is gray or yellowish usually; the consistency variable from hard to soft. The surface is more often

2. Prouzerque, R.: *Arch. de méd. et pharm. mil.* 58:125, 1911.

rough than smooth and may be grooved longitudinally. When multiple the stones may be faceted. The average weight of the calculi is from 5 to 20 gm.

REPORT OF CASES

CASE 1.—*Salivary calculus; right submaxillary; removal from Wharton's duct by incision in floor of mouth.*

History.—Walter T.,³ English, aged 31, stable groom, admitted to the Presbyterian Hospital, Sept. 21, 1904, and discharged, Oct. 14, 1904, three weeks before, while eating, had experienced pain in the right side of the "throat," and noticed a "bunching up" or fulness below the angle of the jaw on the right side. Between meals there was no pain and the swelling became smaller, but every attempt to eat solid food caused an attack of pain and swelling.

Examination.—There was a lobulated swelling in the right submaxillary region. In the floor of the mouth there was a rounded, fluctuating swelling opposite the last two molar teeth. No roentgenogram was taken in this case.

Operation and Result.—September 27, under the mistaken diagnosis of suppurative cervical lymphadenitis, a dissection of the right submaxillary region was made by one of the surgeons. No abscess was found; but a portion of the enlarged and inflamed submaxillary salivary gland was excised. There was no relief from symptoms after this operation, and October 10, I inserted a probe into Wharton's duct to a distance of 4 cm., recognized the sharp click of a calculus, and on opening the duct at this point under local anesthesia, removed a calculus, the size of a small cherry pit (Fig. 1). Four years later, the patient was perfectly well and had had no return of any symptoms.

Comment.—A possible etiologic factor in this case was an alcoholic habit with neglect of mouth cleanliness, although there was no pyorrhea. Also as a groom about the stables, the patient had been in the habit of chewing grain and straws, a particle of which may have entered the duct and acted as a foreign body nucleus.

CASE 2.—*Salivary calculus; left submaxillary; removed from Wharton's duct through floor of mouth (Fig. 2).*

History.—Paul T., aged about 24, born in the United States, soldier, admitted to the hospital, Dec. 23, 1918, had had no previous attacks of a similar trouble. The present illness began about ten days before with a painful swelling in the left submaxillary region. Both pain and swelling were made worse by chewing food.

Examination.—There was a swelling of the left submaxillary gland; and in the floor of the mouth there were elevation and thickening along the course of the left Wharton's duct, with swelling and redness of the papilla.

Operation and Result.—The floor of the mouth was cocaineized, and with some difficulty a whalebone filiform bougie was passed into the duct encountering obstruction at a distance of about 3 cm. The duct was then split open along the probe, and a calculus 1 cm. long was delivered with a small spoon curet. After this there was immediate relief and a rapid subsidence of the swelling of the submaxillary gland. Attempts to roentgenograph this suspected calculus, dental films being used on the floor of the mouth, had been unsuccessful, nor was it definitely palpable with a finger in the mouth.

CASE 3.—*Salivary calculus; left submaxillary; removal from Wharton's duct through floor of mouth (Fig. 3).*

History.—E. R. S., aged 42, born in the United States, clerk, referred to me by Dr. McCastline, and treated in the office, had had attacks of severe pain in the "throat" for from five to six years while eating, accompanied by swelling at the angle of the jaw. The pain was described as of a gripping nature, and there was a sharp pricking sensation along the base of the tongue on the left. Occasionally, he obtained relief by squeezing the floor of the mouth and expressing a "little white plug," after which the pain and swelling would subside. His teeth had been very bad for years. He had

pyorrhea alveolaris, and at the time of examination many teeth were absent and bridges had been inserted.

Examination.—There was a moderate swelling of the left submaxillary salivary gland, which was quite tender to pressure. In the floor of the mouth, well forward near the sublingual caruncle, there was a red, tender elevation which was distinctly fluctuating; no stone could be felt, however. Procain was injected over this area and an incision opened the distended Wharton's duct, permitting the escape of purulent material and a pyramidal calculus measuring 1.3 cm. in length. There was no opportunity for an attempt at securing a roentgenogram in this case. The relief was great and prompt, and the patient has remained well.

CASE 4.—*Salivary calculi (multiple); right submaxillary; removal of two calculi at two operations, from Wharton's duct (Figs. 4 and 5).*

History.—Emil G., Italian, aged 20, carpenter, admitted to the New York Hospital, Oct. 4 and Oct. 30, 1917, had had an attack four years before similar to the present, lasting about three days, but had had no trouble since then until eleven days before admission. While eating he felt pain in the right side of his throat and noticed a swelling below the jaw. This pain and the swelling subsided between meals, but promptly recurred when he ate solid food.

Examination.—There was a moderately enlarged right submaxillary gland. In the floor of the mouth, there was elevation along Wharton's duct; the sublingual caruncle was swollen and reddened, and by pressure over the duct some pus could be expressed.

Operation and Result.—October 4, a whalebone filiform bougie was quite readily passed into Wharton's duct for a distance of 7.5 cm., which must have carried it well back to the gland itself; but while the probe was being passed there was encountered some slight obstruction at a distance of 3 cm. After local anesthesia had been secured, the duct was split open along the probe and a yellowish, laminated calculus was removed measuring 5 by 3 by 3 mm. (Fig. 4).

The patient was readmitted three and one-half weeks later for a recurrence of the same train of symptoms. He stated that after the operation he was relieved for about five days, after which the pains and swelling at meal times recurred. October 30, under local anesthesia, the right Wharton's duct was again incised opposite the last molar tooth and a calculus of the same color and consistency as the first was removed, but it was more than twice as large as the first and measured 1 by 0.5 cm. These two calculi seemed to fit together very well, as if they had originally been parts of one calculus, and yet it is difficult to see how any trauma sufficient to break the calculus could have occurred at the first operation. Four months after operation, the right submaxillary gland was still very slightly larger than the left. The saliva seemed to be discharged in the floor of the mouth at the side of the tongue, where the duct had been split open. One and one-half years after operation, the patient was free from all symptoms.

CASE 5.—*Salivary calculi (multiple); right parotid (Fig. 6).*

History.—Aaron B., aged 52, Russian storkeeper, admitted to the New York Hospital, April 20, 1916, and discharged, April 29, had been under dental treatment for pyorrhea alveolaris for the last five months; the teeth had been in very bad condition. Four months before admission he first noticed a swelling of the right parotid region which was very painful at times and seemed to vary in size. He had experienced a feeling of dryness in the right side of the mouth. For the last week the swelling and pain had been very much worse and constant, and he could not open his jaws.

Examination.—There was a very marked and tense swelling of the whole right parotid gland. In the buccal surface of the right cheek, the opening of Stenson's duct was found to be pouting and reddened and giving exit to creamy pus on pressure on the cheek. The whole tract of the duct felt indurated, but no definite calculus could be detected. A roentgenogram on a dental film placed inside the cheek showed a suspicious shadow of a small calculus.

Operation and Result.—April 20, a whalebone filiform bougie was passed into the right Stenson's duct and a gitting

3. This case was reported by the author in the Annual Report of the Presbyterian Hospital in the City of New York, 1906.

sensation was encountered at 3 cm. Under local anesthesia the duct was split open back to this point, but no calculus could be found. The symptoms persisted, and another effort was made to find the stone, April 24; but at this time there was still so much edema about the duct orifice that no probe could be inserted. April 24, a general anesthetic was given and a horizontal incision was made in the right cheek, exposing the dilated duct, but on palpation no stone could be felt, with the duct directly between the fingers. As it was not deemed wise to open the duct through the cheek, a loop of silk was passed about the duct, and the ends of the loop were pushed into the mouth through the buccal mucous membrane. The external wound was then closed by suture. The buccal surface was then exposed, and with the aid of the traction loop of silk the duct was easily drawn into view and a long incision made into it. A small curet was inserted, but no stone was found.

In this case, as the event showed, the multiple stones had evidently slipped well back into the parotid gland at this time.

On the third day after operation, the patient passed a small soft calculus about 3 by 4 mm., which specimen, unfortunately, was lost. On the sixth day after operation, while eating, he passed a second small and harder calculus about the same size, which is shown in Figure 6. After this there was a remarkably rapid abatement of the swelling, and complete disappearance of all symptoms. The patient remained entirely well during the six months that he was followed.

FREQUENCY OF THE CONDITION

From the various monographs on this subject and collection of case reports, it is fair to conclude that the lesion is rather rare. In 1890, Czygan collected from the literature the reports of about seventy cases. Fütterer later raised this number to 160; Roberg⁴ reviewed 207 cases; and from my own search of reports, I have found enough to make approximately 300, which will very fairly represent the total of cases reported up to this time. The French seem to have encountered or reported these cases more often than any other people.

SITE OF THE LESION

In about two thirds of all reported cases, the calculus has been found in Wharton's duct or in the submaxillary salivary gland. In about 20 per cent., Stenson's duct or the parotid gland has been the site. Only in a considerably smaller number has the sublingual gland been involved. Certainly they occur very much more frequently in the ducts than in the glands.

ETIOLOGY

They usually occur in middle life; only one case is reported as occurring in infancy. The great preponderance of cases are in the male. As the result of inflammation of the duct, concretions may form about masses of bacteria, or salivary corpuscles, and very rarely about foreign bodies, e. g., bits of tartar. Foreign bodies which have been found occasionally occluding a duct include bristles from a tooth brush, bits of grain, and seeds. The lack of mouth cleanliness, and especially pyorrhea with tartar formation,

afford the most likely source of duct irritation and inflammation.

SYMPTOMS

The classical picture of "colique salivaire" of the submaxillary region is that of intermittent swelling of the salivary gland, or of the duct behind the stone, accompanied by sudden severe pain in the floor of the mouth, tongue and side of the throat, all of which occurs during meals or may be excited by the mere sight of food. This tumor persists until there is a sudden discharge of saliva, which in a case reported by M. Reverchon would spout a jet of saliva, occasionally at meals, to a distance of from 30 to 50 cm. In some cases such a history runs back over a period of ten years or more; but in such cases the diagnosis should be very easily made. In many other cases the history is short, of a few months, or a few weeks or even of only a few days.

Cases which apparently start so acutely usually represent the intercurrent of an acute infection of the duct or gland and may be ushered in with acute swelling of the gland, with fever and much local inflammation; and it is here that the diagnosis becomes more difficult.

Pain is always more considerable when the stone is in the duct than when it is embedded in the gland. The general nutrition may suffer markedly because of the dysphagia. Purulent catarrh of the duct and even actual abscess about the duct is not uncommon. The enlargement of the gland due to the salivary stasis is usually of a chronic inflammatory character, resulting in connective tissue formation and atrophy of the gland cells; and only rarely is there actual

suppuration in the gland itself, although it may remain permanently enlarged. Discharge of the stone into the mouth as the first symptom has been rarely reported.

DIAGNOSIS

A number of these patients present themselves to dentists believing that the swelling and pain near the jaw are due to the teeth. And, indeed, an alveolar abscess may be suspected. More of the acute cases are likely to be diagnosed as cases of suppurative lymphadenitis, and treated by external incision. In the cases of chronic enlargement of the gland, malignancy may be suggested.

Examination of the floor of the mouth or cheek will usually show some change at the exit of the duct, a purulent discharge or swelling and redness. There may be a visible swelling along the course of the duct, or bimanual palpation may reveal a cystic mass or even the actual presence of the calculus. In my experience with Wharton's duct, the stone is very likely to be found rather far back, about opposite the last molar tooth.

Probing the duct requires some application and perseverance, but may yield the convincing sensation of "gritting" against the stone. I have found that a whalebone filiform bougie is well adapted for this pur-

Salivary calculi (actual size): 1 to 5 removed from Wharton's duct; 6 removed from Stenson's duct.

4. Roberg, O. T.: Sialolithiasis. *Ann. Surg.* 39, May, 1904; abstr. *J. A. M. A.* 42: 1662 (June 18) 1904.

pose and likely to be more readily obtainable than the very small metal probes which would be necessary.

TREATMENT

After local anesthesia of the vicinity of the duct, one of two methods may be used: First, a probe is inserted and the duct split back as far as may be necessary to deliver the calculus, which may require a spoon curet. Second, a direct incision may be made through the mucous membrane and into the duct at the site of the previously located stone, or into the distended duct behind the stone, or on a probe in the duct.

In the event that the stone has slipped back and cannot be found, the splitting or incision of the duct may permit of its spontaneous delivery within a few days, without further intervention.

Mathews⁵ says that one should be on the lookout for multiple stones, which were present in two of the six cases that he reported, and in two of our cases.

Results are very satisfactory if the obstruction is found and removed, and recurrence is very rare unless a bit of calculus has been left in situ. External incisions are seldom if ever indicated, and are to be avoided.

RHINOPHYMA

A CURE BY A PLASTIC OPERATION WITH A GOOD COSMETIC RESULT

JAMES FRANCIS GRATTAN, M.D.

NEW YORK

Operative removal of rhinophymas has not offered much encouragement to surgeons, judging from the meagerness of the reports on the subject in the literature. The lobular nature of these tumors, with broad bases requiring extensive denudation for removal, and the difficulty of obtaining a satisfactory cosmetic result, without prominent scarring, are factors that have been largely responsible for the discouragement.

My patient was no exception. He had had this disfiguring mass for more than fifteen years. During that time he had consulted surgeons frequently concerning its removal, but none, as he put it, "cared to tackle the job."¹

As can be seen in the accompanying illustrations, the base of the tumor occupied the lower third of the nose, anteriorly and laterally, while the tumor itself protruded forward and downward. To me it offered hope of removal with a reasonably good cosmetic result. I felt that the man was so disfigured by the tumor that he had little to lose. His confidence was encouraging, so we decided to assume the risk together.

REPORT OF CASE

History.—M. G., man, aged 43, single, dated the initial change in the tip of the nose to his tenth year, when, he said, the end of the nose was severely lacerated by a dog bite. He did not recall whether or not there was infection present at that time. At 11 or 12 years, the patient had facial erysipelas

involving the cheeks, eyelids and nose. This attack kept him in bed for two weeks. During his youth he sustained several bad blows and falls involving the nose.

Two and a half years before we saw him he had had a second attack of facial erysipelas. The venereal history presented nothing of interest in relation to the local condition.²

Physical Examination.—The patient was of medium build and, aside from the nasal tumor, apparently without lesions, deformities or organic disturbances. There was a globular tumor about 1¼ inches in diameter, almost a perfect sphere, with a base almost as broad as the diameter of the mass, and extending upward on the anterior surface to the junction of the middle and lower thirds of the nose, and laterally to the anterior borders of the alae nasi. Chronic acneiform lesions (comedones and sebaceous cysts) dotted the skin over the entire tumor surface and involved the skin of the rest of

Fig. 1.—Lateral aspect of the tumor.

the nose and the adjacent parts of the cheeks. These lesions are evident in the illustrations. The skin of the tumor was leathery and firmly attached, but of normal color.

Operation and Results.—One-quarter grain of morphin, with ⅓ grain of atropin, was given forty-five minutes before the operation. The entire face was cleansed with naphtha to remove the excessive sebum, and subsequently wiped with 95 per cent. alcohol, followed by ether. A sterile dressing was applied and left in place until the patient was brought to the table. The skin, including the forehead, nose, cheeks and upper lip, was then painted with 2 per cent. iodine. The surface deposit of iodine was wiped off with 95 per cent. alcohol. Twenty-five per cent. argyrol was dropped in the eyes and nostrils, and the mouth was painted with the same solution. Moist, sterile towels were draped over the

2. The history of repeated traumas and infection is of value only in the vague sense in which are associated repeated irritation and tumor growth.

5. Mathews, F. S.: Submaxillary Calculi. *Ann. Surg.* 63: 140 (Feb.) 1916.

1. The patient was referred to me by Dr. Daniel O'Leary, of Newburgh, N. Y. Dr. O'Leary and I had intended to operate on this man at Newburgh but owing to Dr. O'Leary's disability, by reason of an infected finger, he sent the patient to New York, fearing that he would change his mind about being operated on.

surrounding areas, and the patient was instructed to breathe through the piece of sterile gauze placed over the mouth. Two per cent. procain was infiltrated at the alae, columella and across the nose above the tumor.

A U-shaped flap was made above, beginning at each ala and including about one-half inch of the skin on the superior surface of the tumor mass. An inverted U-shaped flap was made on the inferior surface of the nose, including the skin of the entire inferior surface of the tumor. The ends of the two U-shaped incisions were made to meet at each alar crease. The flaps thus outlined were dissected off the tumor with considerable difficulty, both because of the leathery quality of the skin itself and because of its firm attachment, or rather inclusion in the tumor. The skin flaps having been freed, the tumor was dissected in a wedge-shaped manner from the underlying nasal cartilage. There was considerable fibrous tissue in the tumor and no distinct differentiation between the tumor and nasal structure. The dissection was rather difficult on account of these conditions. Considerable bleeding of both arterial and venous character was encountered. This was controlled by suture-ligatures of fine catgut. The inferior flap proved one-fourth inch too large and was trimmed to fit

Fig. 2.—Anterior aspect of the tumor.

the upper flap. The lower flap was rolled up over the edge of the nose so that the suture line ran directly across the anterior surface of the nose from ala to ala. The upper flap was very difficult to adapt to the new contour, as it had stood out at a right angle to the anterior nasal line during the long period that it had performed the function of covering the upper surface of the tumor. The adaptation was begun by fastening it at its center to the center of the lower flap and then adapting the sides by trimming and scoring the edge, fitting and refitting several times, until the best possible approximation was obtained. In this way a rather well-shaped nose was molded out of very discouraging material. Interrupted sutures of fine silk were used. These were removed on the fourth day. The tension was relieved by sterile adhesive straps. The result one month subsequent to operation is shown in Figures 3 and 4.

The wound healed by primary union and the patient left the hospital on the tenth day. Aside from slight redness and the prominence of the sebaceous gland orifices, the nose had the appearance of a normal organ. The problem of improving the condition of the skin was discussed in consultation with Dr. Fred Wise. Dr. Wise suggested the use of 50 per cent. trichloroacetic acid, applied periodically, until the higher prominences of the skin were leveled. The appearance of the nose

after the first application of this acid had completed its good work is shown in Figure 3. The whiter, smoother areas represent the portions thus treated. This treatment was repeated until all areas of the nose had been smoothed out, and the

Fig. 3.—Lateral aspect after plastic operation.

result is most satisfactory. Four applications were made in all. Subsequently, exposures of the roentgen ray at three week intervals were given with the idea of further improving the condition of the skin and keeping in abeyance any tendency to recurrence of growth in the tissues treated.

Fig. 4.—Front view after operation.

PATHOLOGY

According to the best dermatologic opinion, rhinophyma is a further developmental stage of acne rosacea. Because of the persistent hyperemia and

irregular periodic aggravations, the vessels become permanently enlarged. A hypernutrition of the skin results. The sebaceous glands hypertrophy first as gelatinous nodules, later becoming fibrous. Acne lesions are sometimes superadded. The markedly hypertrophic forms are due to new connective tissue growth, amounting to a real hyperplasia. Follicular suppuration with new connective tissue formation results in distention of the veins, so that they amount to actual sinuses. In this case the prominent pathologic features were the marked acneform lesions of the surface (comedones and small sebaceous cysts), the excess of fibrous tissue rendering the mass firm and elastic, and the prominence of the blood vessels, particularly the veins.

The result has been most satisfactory to the patient and to me, and there is no reason to believe that the nose will not remain in its present good condition. The illustrations reveal more clearly than any description the complete change in the physical appearance of the face. The condition of the skin has improved greatly since that represented in Figure 3, as a result of the trichloracetic acid treatment.

COMMENT

To me this case demonstrates the desirability of attempting something for the improvement of conditions of this type. It is impossible to estimate the good effect of the result on the patient's mentality and outlook on life, to say nothing of the physical betterment.

24 West Fifty-Ninth Street.

HYPERTRICHOSIS

REPORT OF CASE

ANDREW J. GILMOUR, PH.D., M.D.

Attending Dermatologist, New York City Children's Hospital and Schools; Consulting Dermatologist, Manhattan State Hospital; Consulting Dermatologist, Englewood Hospital

NEW YORK

Hypertrichosis is either an abnormal or an excessive growth of hair. In some cases the hairs may be increased in size; in others, the number of hairs may be increased, or both conditions may be present. This abnormality may either be referable to the location on the patient's body or dependent on the age or sex of the individual. There may be either a racial or a family predisposition to this condition. Brunettes are more prone to hypertrichosis than blondes.

This anomaly is classified as acquired and congenital. The acquired type is generally not an extensive condition; it may be universal or partial—usually the latter. An example of the partial is the growth of a beard on a female subject. The congenital condition is comparatively rare. An example of the universal type was Jo Jo, the dog-faced boy, whose face resembled that of a terrier and whose body was covered with soft hair. The congenital variety is usually of the partial type, and often manifests itself as a hairy pigmented nevus. A favorite location for this is at the lower end of the spine over the sacrum. The case here reported is of the congenital partial type.

It is unusual in that so far as macroscopic examination can determine, the hair is growing from perfectly normal skin, indistinguishable from the adjoining skin where the hair is present.

REPORT OF CASE

M. S., woman, aged 30, housewife, married, Italian, with negative family history, was born with a growth of soft hair a few inches long, situated over the small of the back. This hair gradually increased in length and became coarser, so that it is now similar to the hair of the head, though the texture of this hair is a little softer. The color is the same as that of the head, a dark brown. The hair is growing from a perfectly normal skin; there is no pigmentation; no hypertrophy of the skin or other sign of nevus is present.

Area of hypertrichosis.

For the last eight or ten years the patient has cut off this hair about every twelve months. The hair now present is 8 inches long and has been growing for one year. The growth has never been much longer than at the present time. The area covered by the hair has a diameter of from 4 to 5 inches.

The condition described was accidentally discovered while the patient was being given an intramuscu-

lar injection of mercuric salicylate for syphilis. A roentgenogram of the lower end of the spine is negative. * The patient is of a highly neurotic type.

133 East Fifty-Seventh Street.

Clinical Notes, Suggestions, and New Instruments

A NEW BLOOD COAGULOMETER*

GEORGE KING, M.D., AND H. A. MURRAY, JR., M.D., NEW YORK

Authorities on blood coagulation, including Howell, Morawitz, Lee and Hurwitz,¹ have asserted that only clotting tests in which the blood is collected by venipuncture can be depended on to give reliable results. Blood taken from a finger prick is unavoidably mixed with more or less tissue fluid, which apparently precipitates the clotting process even in cases in which the power of the blood to form a gel is known to be impaired. Therefore, it seems that if tests made in this way are relied on many hemorrhagic conditions will go undiagnosed. Not long ago there was a "bleeder" in the wards of the Roosevelt Hospital who repeatedly gave a normal clotting time with blood drawn from finger stabs. Although hemophilia was suspected, it was only when venipuncture was resorted to that confirmatory evidence of this disease was obtained.

Last spring in doing some work which involved clotting determinations, we had occasion to study this subject. It was found that in 1911, Solis-Cohen had summarized the results of more than thirty different tests reported in the literature.² But because in all of them blood from finger pricks was used, they had to be disregarded and attention directed solely toward procedures calling for venipuncture. We tried the more suitable ones described in various publications and also had the opportunity to interrogate Professor Howell, who

2. Solis-Cohen, Myer: The Coagulation-Time of the Blood as Affected by Various Conditions, Arch. Int. Med. 8:684 (Nov.) 1911; ibid 8:820 (Dec.) 1911.

admitted the uncertainty of prevailing methods. As an example, he told how on one occasion blood drawn by venipuncture into a hypodermic syringe containing a few drops of physiologic sodium chlorid solution, and then divided equally between two similar test tubes, had clotted ten minutes faster in one test tube than in the other. At the Presbyterian Hospital, New York, the coagulation time of the blood is usually tested by allowing it to drop freely into a paraffin-lined test tube from a Luer needle introduced into the median basilic vein. The instant at which the tube may be completely inverted without dislodging the clot is considered the end-point. Normal figures by this method have been found to vary from four to twenty-seven minutes.

In our own experiments, we were not able to attain conformity of results with any methods examined, no matter how carefully the instructions were followed. The tube pictured in the accompanying illustration was then devised, and has given more consistent findings in our hands than have other procedures. The tests were performed largely on dogs, whose blood is very readily collected by puncture of the external saphenous vein. In more than thirty tests, with one exception, all the samples of blood from animals in apparent good health clotted in between nine and twelve minutes. The average was ten and one-half minutes. Any technic, however, seems to be relatively accurate when employed repeatedly by the same man, particularly when that man has devised the test himself. The sense of proprietorship apparently calls for thoroughness and devotion to detail which finally leads to a technical precision impossible under less stimulating circumstances. To avoid this possible personal element and properly to subject this instrument to trial, tubes were distributed among a few hospitals and tested without any special care or previous experience by various interns and medical students. The tubes were accompanied by these instructions:

METHOD FOR TESTING COAGULATION TIME OF THE BLOOD

The coagulometer to be used is composed of the following separate parts:

1. Glass tube, length 9 cm., inside diameter 9 mm. (A line to indicate the level taken by 2 c.c. of fluid within the tube is etched on the glass.)

2. One-way stopcock.

3. Luer needle with wire inserted, length 1 inch, gage 20. (These may be purchased from James W. Dougherty, 413 West 59th Street, New York City.)

A. Preparation of Coagulometer.—The tube is thoroughly cleansed with potassium dichromate cleaning mixture and then rinsed out with water, alcohol and ether in the order named. When it has become absolutely dry its upper wide open end is plugged with cotton. (The cleansing is usually done immediately after a test, and the tube kept in a glazed envelop or desiccator ready for use. It is important that the inner surface of the tube be smooth and absolutely clean, as little specks of dust make a difference in the clotting time.)

After the Luer needle in a test tube has been sterilized in the autoclave, attach it to the stopcock and the latter to the glass tube. Open the petcock. The coagulometer is now ready for use.

B. Procedure.—The skin overlying the vein of the patient to be punctured is sterilized with iodine. (One of the veins at the elbow is usually selected, and in that case the arm of the patient is hung over the edge of the bed.)

Put in plain sight a watch with a second hand, and note the time of applying the tourniquet. After thirty seconds, enter the vein from above downward, with the stopcock of the coagulometer open. When blood first appears in the tube, record the time. During the procedure the tube is kept in a vertical position with the lumen of the needle in the direct current of the vein. (It is believed that the ease and speed with which the vein is entered is an indeterminate variable personal error of some consequence. Therefore, if there is difficulty in entering the vessel, the needle should be changed and a second attempt made with another vein.) When the blood has reached the 2 c.c. mark, shut off the flow by turning the stopcock.

Remove the instrument from the vein, separate the needle, and stand the tube with attached stopcock in a rack or vessel for six minutes. (This should be done quickly and evenly. Do not tip, twist or shake

Blood coagulometer.

the tube.) If the temperature of the room does not lie between 65 and 90 F., the tube should be kept during the test in a water bath whose temperature is maintained at about 75 F.

The coagulation time is the time elapsing to the nearest one-half minute from the instant blood first appears to the moment when the tube may be gently but completely inverted without displacing the clot from its bottom. After six minutes have elapsed, test the tube every minute until the blood shows signs of clotting; then test every one-half minute. After twenty-five minutes, if the blood has not clotted, test every five to ten minutes.

In testing, one should avoid breaking the surface clot by rough handling or extreme tipping. At first the tube need only be tipped to the slightest degree to make the fluidity of the blood clearly apparent. It should not be upset until it is quite evident by holding it in the horizontal position that it will not be disturbed by this maneuver.

After completing the test, the needle and stopcock should be cleared of fibrin threads and other matter by the use of a wire, followed by rinsing in hydrogen peroxid, alcohol and ether in the order named. If the stopcock does not turn easily after the washing, add a drop or two of xylene (xylol).

RESULTS

As was expected, the results obtained from these various sources were not uniform, but under the circumstances they were considered satisfactory. At Roosevelt Hospital, twenty supposedly normal patients were tested. The coagulation time varied from eight and one-half to fifteen minutes. The average was eleven minutes. The time in fourteen cases was between nine and eleven and one-half minutes. In three cases of jaundice the time was eighteen, twenty-two and twenty-eight minutes, respectively. Only a few results were received from the Presbyterian and Bellevue hospitals, but the time in all of these in which the proper technic was observed was between the outside limits (eight and fifteen minutes), and averaged about eleven minutes. The results from all our estimations, animal and human, show that, by this method, ten and one-half minutes may be considered the average time for clotting, with eight and fifteen minutes as the outside limits.

ADVANTAGES

The method here presented seems theoretically to allow for nearly the minimal personal error. It is simple, and practically has given rather consistent findings. The end-point, of course, is indefinite; but until the physicochemical mechanisms involved in blood coagulation are discovered, a completely satisfactory test need hardly be expected.

PREGNANCY IN THE RUDIMENTARY HORN OF A BICORNATE UTERUS

GEORGE L. BRODHEAD, M.D., NEW YORK

DeLee¹ states that pregnancy in the rudimentary horn of a bicornate uterus resembles ectopic gestation very closely, the first case being recorded by Mauriceau and Vassal in 1669, since which time more than 100 cases have been reported. The rudimentary horn may be closed at either end, making pregnancy impossible but accumulation of menses probable. Should the fertilized ovum be inserted in the small horn, there is no hope of reaching the uterus, because the connecting bridge of tissue is usually imperforate. The ovum may grow to term, but the gestation sac usually ruptures in early pregnancy, and severe internal hemorrhage follows.

REPORT OF CASE

History.—A quintigravida, aged 30, had had four normal confinements, the last of a half hour's duration. The present pregnancy had progressed to about the eighth month, the only symptom being occasional pain in the left hypogastrium. On the day of admission to Harlem Hospital, there had been slight pain in the left half of the abdomen at 7 a. m., and the patient complained of slight occasional pains up to the time of her admission at 2:30 p. m. No life had been felt for two days before admission, and the midwife who was called in diagnosed death of the fetus, for which reason the patient was referred to the hospital. At about 3 p. m. she was apparently in good condition, but at 3:15 she was found in shock, pulseless. My associate, Dr. Langrock, who saw the patient first, gave 1,200 c.c. of saline solution intravenously, but the condition of the patient when I arrived a

1. DeLee, J. B.: Principles and Practice of Obstetrics, Ed. 3, Philadelphia, W. B. Saunders Company, 1919.

short time afterward was desperate, and in a few minutes she died. Abdominal palpation revealed a fetus apparently free in the abdominal cavity, and the cervix was soft and closed. A diagnosis of ruptured abdominal pregnancy was made, and a postmortem abdominal section was performed.

Fig. 1.—Anterior view of the uterus, which is seen to the left, with the normal right ovary and tube, and the fetal sac to the right. The membranes can be seen attached to the edge of the placenta, a portion of which is visible on the extreme right. The small slit in the right side of the fetal sac is the point from which Section 2 was taken. The fimbriated extremity of the left tube is seen extending downward and to the left from the fetal sac.

Necropsy.—A large amount of blood, with the child, was found in the abdominal cavity. The child weighed 4½ pounds and was dead, though showing no maceration. It was impossible to determine the exact variety of pregnancy without thorough microscopic examination of a number of sections, and this has been done for me by Drs. Strong and Schwarz of the Woman's Hospital.

Diagnosis: Their diagnosis was: uterus bicornis, with rudimentary horn and pregnancy of approximately eight months' duration in this horn (decidua in the uterus, corpus luteum of pregnancy in left ovary).

Fig. 2.—Posterior view of the uterus, which has been incised, and the small pedicle connecting it with the fetal sac. The fimbriated extremity of the left tube is again seen in the lower portion of the illustration, with the ovary just above. The fetal surface of the placenta is to the left of the depression in the middle of the fetal sac, and the umbilical cord is seen attached to the placenta at the upper left angle of the illustration.

Macroscopic Examination: The corpus uteri was asymmetrically developed and measured 10 by 5 by 4 cm. The adnexa of the right side showed no gross changes. On the left side of the uterus there was a pedicle of about 5 cm.

length and 1 cm. diameter attached to the side of the uterus at the level of the internal orifice. This pedicle connected a fetal sac of approximately 18 cm. diameter with the uterus. The ovary and fimbrial extremity of the tube of this side (left) were found attached to the fetal sac. The fimbriated extremity was perfectly free. The ovary contained a large, fully developed corpus luteum. The fetus measured 40 cm. in length, and was well preserved. The amnion showed a large lacerated opening through which the fetus with cord escaped into the abdominal cavity.

Microscopic Examination: Section 1, taken from a structure which appeared to be the round ligament, showed a lobulated muscle bundle (round ligament).

Section 2, taken from the fetal sac, showed uterine musculature with a small number of round cells and syncytial wandering cells. It also showed the decidua spongiosa without any fetal elements.

Section 3, taken from the right tube corner, showed muscular ligament tissue.

Fig. 3.—Cross-section of rudimentary horn of bicornate uterus (Section 5).

Section 4 showed the fimbriated extremity of the left tube, normal. No tube could be found on the left side.

Section 5, taken from the pedicle dissected out of its cover of broad ligament, showed three strata of smooth musculature, circular and longitudinal, the inner layer showing a marked decidual reaction. The center of this musculature layer contained a narrow circular lumen which was lined with a single row of cylindric epithelial cells.

INTERESTING FEATURES OF CASE

1. The patient had been pregnant four times in the right horn of the uterus before becoming pregnant in the rudimentary left horn.

2. The left ovary contained the corpus luteum of pregnancy and there was a well marked fimbriated extremity of the left tube, but no tube could be discovered.

3. The uterus appeared to be no larger than the usual size before pregnancy, and seemed to have developed chiefly from the right müllerian duct.

50 West Forty-Eighth Street.

FOLDING CHAIR FOR SPINAL PUNCTURE

NORMAN E. WILLIAMSON, M.D., STOCKTON, CALIF.

Pathologist, Stockton State Hospital

The chair that I described recently in *THE JOURNAL*¹ is not readily portable; and as I had to perform spinal punctures away from the operating room, I devised a folding chair that

Chair for spinal puncture, folded and open.

can be easily taken in the automobile. The inconveniences and dangers of the old method are emphasized when one has become accustomed to using the chair for spinal puncture.

At the right in the accompanying illustration the folding chair is open with half the braces in position; the other braces are set at an angle to show the method of adjustment. The chair weighs 33 pounds.

One point should be emphasized: The angle of flexion of the thighs on the pelvis when the patient is in the chair prevents any forcible movement of the thigh and assists greatly in steadying the patient.

ABDOMINOTHORACIC WOUND WITH EVISCERATION OF SPLENIC FLEXURE

FRASER B. GURD, B.A., M.D., MONTREAL

This report of a soldier who came under my care in June, 1919, is of more than usual interest, both as regards the extensive interference to which his gastro-intestinal tract has been subjected, and as regards the repair of a severe injury of the left diaphragm.

History.—Private A. G. P., aged 37, was wounded, Oct. 2, 1918, by a large shell fragment which tore through the lower portion of the left chest, destroying about 5 inches of both the seventh and eighth ribs in the axillary line. The diaphragm was torn and the splenic flexure protruded through the opening. At the primary operation performed at the clearing station, the loop of splenic flexure was opened and the pleural and peritoneal cavities were closed. This opening in the splenic flexure acted as an artificial anus until November 11, when a laparotomy was performed, the ileum divided and the distal end closed, and the sigmoid divided and proximal end closed. An end-to-end anastomosis between the ileum and the distal portion of the sigmoid was performed, with a view to short-circuiting the artificial anus.

1. Williamson, N. E.: A Chair for Spinal Puncture, *J. A. M. A.* 74: 602 (Feb. 28) 1920.

November 30, the patient developed acute obstruction. At operation a large pelvic abscess was found with much matting of loops of small intestine. These were separated, and the abscess was drained. A lateral anastomosis between the ileum and the transverse colon was performed, as there was doubt regarding the free passage to the anus, and the small intestine was greatly distended. Convalescence was uneventful. The bowels moved chiefly by rectum.

Condition on Admission.—When the patient entered St. Anne's Military Hospital, June 22, 1919, his general condition as regards nutrition was fair, and his color good. Mentally he was very dull and melancholy. It seemed to be impossible for him to think of anything other than the fecal discharge from his side. With the exception of marked limitation of respiratory effort of the left side of the chest, and diminished breath sounds, examination of the chest was negative. Examination of the abdomen revealed separation of the right rectus muscle at the site of a long laparotomy incision. At this point there was bulging. In the center of the weakened area the muscle was separated 7.5 cm. Over the lower part of the left lower costal area, in the axillary line, there was a large scarred area approximately 16 by 20 cm. in diameter, in the center of which there was an elliptic scar covered by mucous membrane 10 by 7 cm. in size. On examination with the finger it was possible to enter the bowel at two points, the one opening entering the distal portion of the transverse colon, the other the proximal portion of the descending colon. Portions of the seventh and eighth ribs were apparently missing.

The patient was wearing a special corset, both for the support of the abdominal hernia and to retain the dressing over the discharging anus. Approximately one quarter of the fecal discharge escaped into the flank, three quarters being passed normally. The fecal discharge from the side was practically free from odor, and caused no excoriation of the skin.

Despite the fact that the papers accompanying the patient from England advised strongly against further operative interference, it was determined that in view of the intolerable condition in which the patient found himself, his discharge

Fig. 1.—Condition of patient before operation.

from the army in this state without some further attempt to improve his condition should not be accomplished.

Operations and Result.—August 6, an incision was made along the mucocutaneous border encircling the protruding intestine, which was dissected from the underlying tissue. The posterior surface of the intestine was found to be covered by peritoneum with the mesocolon intact. Above, the pleura was fixed to the deep surface of the protruding intes-

tine, and below, the peritoneum was likewise attached. Both pleural and abdominal cavities were opened and packed off. It was found that the mesocolon was replacing the diaphragm, and hence divided the pleural from the peritoneal

Fig. 2.—Condition of patient on discharge.

cavities. The splenic flexure was cut across, and the proximal end closed by a Connell suture and invaginated by a double purse string. The stump of the proximal colon was sutured to the parietal peritoneum. The distal segment of the intestine was pulled well out of the wound and wrapped

Fig. 3.—Course of intestinal contents after: (1) original wound; (2) first short-circuiting operation; (3) second short-circuiting operation, and (4) closure of artificial anus.

in paraffin gauze. The parietal peritoneum was separated somewhat from below and sutured to the cut edge of the mesocolon. The pleura was sutured to the upper edge of the mesocolon, thus reestablishing the mesocolon as an artificial

diaphragm. Poorly nourished scar tissue surrounding the original artificial anus was excised. As a result of this removal of scar, and more particularly as the result of the removal of the bowel from the opening, all sutures were found to be under great tension. In order, if possible, to prevent the breaking down of the wound and the opening of both pleura and peritoneal cavities, double No. 4 chromic catgut was passed above the fifth and below the eighth ribs. The patient was postured so as to bring these ribs into as close contact as possible, and the sutures were pulled tight. Following this procedure, the entrance of air into the pleural cavity was arrested.

A flap of skin and subcutaneous tissue with its pedicle behind was turned down from the upper part of the chest and sutured over the operation area. The corners of the denuded area were sutured to prevent retraction. A small paraffin gauze drain was passed beneath the flap of the skin to the proximal stump of the intestine, and the denuded area was covered with a bismuth iodoform petrolatum paste dressing. The wound was dressed at four day intervals.

The transplanted flap healed by first intention. On the tenth day the sutures were removed. The site from which the flap was removed was found covered with healthy granulations. The general condition of the area operated was found to be very satisfactory.

On the seventh day following operation the patient, who at all times was difficult to control, walked for his midday meal, a distance of half a mile to the Red Cross hut.

Fig. 4.—Operative field.

August 29, a radical repair of the abdominal hernia was performed. The raw surface of the chest was grafted (Thiersch). The free end of the colon was excised, and the free edges were sutured to the abdominal wall.

September 9, the abdominal sutures were removed. There was a practically complete "take" of the skin graft. After the operation the patient's condition was very satisfactory. By October 15, on which date he went on leave, he had gained 17 pounds, and was bright and mentally alert.

Condition on Discharge.—On discharge from the service, Dec. 1, 1919, he had gained 30 pounds, and will apparently make a useful citizen. A small patch of mucosa representing the upper end of the splenic sigmoid pouch is discharging very little mucus. A roentgenogram demonstrates that no barium enters the ascending or transverse colon. There is marked limitation of respiratory effort on the left side. The patient is free from pain, discomfort or digestive disturbance, and he no longer finds an abdominal support necessary.

115 Stanley Street.

Loss of Health.—The transition from vigor to health, from health to impairment, and from impairment to disease is gradual, almost imperceptible. The loss of vitality does not take place abruptly, suddenly, in ways that stagger and arrest one's attention, but our vital losses, like our financial losses, are in dribbles, in pennies, nickels and dimes, and occasionally quarters. And in the one case, as in the other, we do not become alarmed until our surplus is dangerously drawn on.—W. S. Rankin, *Tr. Assn. Life Ins. Presidents*, 1919.

A NEW TONSIL INSTRUMENT

J. G. ROHRIG, M.D., BENNETT, IOWA

The tonsil enucleator is not a snare, nor is it a cutting instrument or a guillotine. It has a dull blade with an oval shaped opening. The ring encircling this opening is an incomplete one having a 5 mm. gap in its lower part, as shown at A in Figure 1.

Fig. 1.—Tonsil enucleator: A, gap for passing over tonsil forceps; B, position when gap is hidden and ring is ready for passing over tonsil.

This gap is hidden, and the ring a complete one when the blade is in the position shown at B in Figure 1. By this gap the enucleator may be hooked over the tonsil forceps while the latter keeps its grasp of the tonsil, as shown in Figure 2. The handles are then pressed until the catch on the lower part of the channel supporting the blade is felt to engage the notch on the lower edge of the blade. The ring is now again a complete one encircling the tonsil forceps, as in Figure 3.

The tonsil being held by a good grasp of the forceps secured before the dissection of pillars is begun, the enucleator is instantly placed in position, as shown in Figure 3. The ring is passed well down behind the superior lobe of the tonsil while the distal part of the ring is brought well out to include the inferior lobe, or pole. By pressure of the handles the dull blade is moved, and the entire tonsil with its capsule is peeled out with as little injury to blood vessels and tissues as is possible. The distal part of the blade can be passed well outward to include the inferior pole of the tonsil, while a wire loop cannot be passed beyond even a slight obstruction. The first grasp of the tonsil by the tonsil forceps should be sufficiently deep to engage the fibrous trabeculae, which gives a good bite that will not tear out, and no further laceration or grasping of friable superficial tissue is needed. With a good bite, the pillars are dissected, the upper and anterior part of the tonsil with the capsule is loosened, the enucleator is applied and placed to include

Fig. 2.—Tonsil enucleator being hooked over tonsil forceps.

Fig. 3.—Completed ring after tonsil enucleator has been placed over forceps; handles are pressed until it is felt that catch has engaged notch.

the lower pole, and the operation completed without a second grasp. Even after it is constricting the tissues, the enucleator may be instantly removed from the throat, if it is desired to dissect a pillar. The little dissection may be done, and the enucleator replaced instantly. This cannot be done with a wire loop. Not only does the dull blade better follow the irregularities of the capsule than does a sharp edge or a wire loop, but, in addition, the crushing division by the dull blade is followed by less bleeding, and less opportunity for

organisms to gain entrance to the circulation, than if division of tissue were by sharp edge or wire.

This method does not require outward pressure in the direction of the angle of the jaw to bring the tonsil into the ring of the instrument, and therefore the surrounding tissues are not traumatized. Trauma to these structures is not desirable, especially if active organisms are present at the time.

A NEW AND EASY METHOD FOR DEMONSTRATING SPIROCHAETA PALLIDA

S. D. COFFIN, A.B., M.D., SEATTLE

A piece of passe-partout or black paper, the size of a quarter, pasted on the bottom of the Abbé condenser of the ordinary microscope will facilitate the making of dark field examinations for *Spirochaeta pallida*. I have employed this method for the last six months, and found it even better than the regular "dark field" attachment sold for the purpose.

A hooded light of 100 watts, about 8 cm. above the work bench, is employed. A piece of black passe-partout binding, the size and shape of a quarter, is pasted on the center of the lower (convex) surface of the Abbé condenser, the top of which should be level with the top of the stage of the microscope. The high (4 mm.) objective is used. The specimen should be thin, and evenly distributed between the coverslip and the slide. Care should be taken to wash the lesion only with cold water. Strict instructions should be given to the patient not to put any medicines, even soap, on it until

Fig. 1.—Method for demonstrating *Spirochaeta pallida*: A, side view of Abbé condenser; arrow points to black paper; B, bottom view.

Fig. 2.—Hood for light.

the diagnosis is made, for even the mildest antiseptics make it impossible to find the spirochetes.

Heavy liquid petrolatum is used between the slide and the upper surface of the condenser. Oil should not be used on the upper surface of the specimen, that is, the high, dry lens should be used.

The light is regulated with the lower shutter of the condenser till the field looks like the clear sky on a moonless night. Two fields will be found; one should rack slowly through the first field to the second, where *Spirochaeta pallida* will be beautifully demonstrated.

201-204 Yale Building.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

SATURDAY, MAY 22, 1920

It is unnecessary to remind our readers that periodical publishers are at present living under a sword of Damocles. In this instance the sword is "paper shortage." It has been the rule of THE JOURNAL to keep a six to eight weeks' supply of paper on hand in order to be ready for emergency, but, because of freight difficulties, this reserve has gradually dwindled almost to the vanishing point. Somewhere between the paper mills and Chicago there are more than a hundred tons of paper en route to THE JOURNAL. One car was shipped more than six weeks ago and others have since followed at regular intervals. This announcement is made so that our readers may have explained beforehand any contingency which may occur: It may be that THE JOURNAL will be sent out in a thin paper cover; it may be necessary temporarily to reduce the number of pages; there is a bare possibility that some issue may be seriously delayed.

BEE POISON

The mention of animal poisons—so-called zootoxins—is likely first of all to bring to mind the venoms of snakes. This type of highly toxic substances has been extensively investigated, notably by Flexner and Noguchi¹ in this country. The effects produced by venoms are varied and undoubtedly due to a number of distinct components, including hemotoxins (that is, hemolysins and hemagglutinins), neurotoxins, endotheliotoxins and leukocytolysins. Their precise chemical nature has not yet been ascertained. In addition to these harmful products, practical medicine has to deal with the poisons of various insects: scorpions, spiders, centipedes, ants, wasps and bees.²

Bee poison is probably encountered most frequently. Fatal intoxication in man as a result of the sting of bees is by no means unknown. The bee poison has awakened the interest of investigators, not merely because its effects need frequently to be counteracted in persons who have been stung, but also because it

formerly acquired some reputation as a therapeutic product, with a history of many years' standing. The sting of bees has been recommended in many parts of the world, usually as a suggestion of popular lay therapy, for palliating a great diversity of disease conditions, among which rheumatic disorders stand foremost. Even physicians have not been averse to the trial of treatment with bee poison, and there are records of patients subjected to increasing numbers of "bites" up to a total of fifty, or even a hundred, a day. In such cases the effects have been far more pronounced than mere local manifestations of bee sting.³

It is no longer satisfying to the inquisitive worker to designate a harmful substance, such as may be contained in the bite of an insect, by the vague name of toxin. Students now demand some knowledge of the chemical nature of the toxins. Are they protein in nature, so that the possibility of developing antitoxic substances may be reckoned with? Or are they well defined organic or inorganic compounds for which a chemical antidote can be secured? These are the sorts of questions that are likely to be asked nowadays in considering animal poisons. From the standpoint of the investigator, some of the difficulties become evident when it is recalled that the secretion of a honey-bee represents at best 0.0003 or 0.0004 gm. ($\frac{6}{1000}$ grain), two thirds of which is water. The residual substance is known to include a variety of compounds, including considerable protein.

That the poisonous component of the toxic secretion of the bee is not a protein was shown by Langer.⁴ This discovery made it highly improbable that an immunity to bee poison can be developed through the usual mode of antibody production, as this type of biologic protective response is usually, if not always, associated with protein antigens. Immunity of some sort undoubtedly does exist, if one may trust the personal testimony of beekeepers. Bee poison is known to be markedly hemolytic; and its potency in producing severe inflammatory reactions, with edema and necrosis, has been demonstrated beyond doubt. These different phenomena are usually associated with potent agencies of quite unlike chemical character.

The latest information contributing to the explanation of the action of the bee poison is the outcome of studies by Flury,⁵ who has actually worked with the product from several hundred thousand bees. Langer had believed that the protein-free bee poison was a nonvolatile organic base. Flury regards it as a compound of far greater complexity. A considerable part seems to be lipoid in character. By hydrolysis it has been possible to split off cholin, glycerol, phosphoric acid, palmitic and other fatty acids, an indol deriva-

tive, presumably tryptophan, and an unidentified non-nitrogenous component. Some of these disintegration products are undoubtedly derived from phosphatids like lecithin. The last mentioned non-nitrogenous fragment is assumed to be the pharmacologically active component of bee poison. It can produce hemolysis, and behaves like the hemolytic saponins. In view of these findings Flury regards the bee poison, in its natural form in the secretion, as a complex of lecithin with basic components, showing resemblances to the protein-free sapotoxins, on the one hand, and to poisons of the cantharidin type, on the other. Snake venoms also include saponin-like poisons which account for their hemolytic properties. The potency of cantharidin as an irritant poison helps to explain the hyperemia and attendant symptoms that bee stings call forth.

THROMBOPLASTIC PRODUCTS

It has long been known that most tissues furnish something that can play a potent part in the coagulation of the blood. In the usual process of clotting which occurs after a hemorrhage and thus represents one of the most effective protective mechanisms of the body, contact with tissues inevitably occurs. The blood itself, as it exists in the circulation, remains fluid under normal conditions because it lacks active thrombin, one of the essential factors in the clotting process. It has often been pointed out that if the plasma could be removed from the blood vessels without coming into contact with tissues and without destruction of any of the formed elements of the blood itself, it would tend to remain fluid as it exists within the vessels. Experimentally, plasma has been secure in this way; it clots promptly on addition of tissue extract.

The possibility of controlling hemorrhage more effectively in some cases by supplying a thromboplastic substance, as the tissue factor has been designated, long since suggested itself. Obviously, such a therapeutic procedure could not be expected to promote a successful outcome unless all the other essential factors—fibrinogen, calcium, etc.—were also present in adequate amount. Attention was directed some time ago to the use of extracts of tissues or certain cells, notably the blood platelets, in the attempt to produce effective hemostatic products. Some of them have already been the subject of patents.

The probability that the active component in tissue extracts is lipoid in nature was suggested by earlier investigators. In 1912, Howell¹ of Johns Hopkins University reached the conclusion that the thromboplastic substance is a phosphatid, which he subsequently identified with cephalin. Following this lead, commercial thromboplastic products have commonly been prepared from brain tissue, a material known to be rich

in cephalin.² Whether they shall find a permanent place in therapy remains to be seen. Recently, however, Mills³ of the University of Cincinnati has found lung extracts to be more active as thromboplastic agents than are the extracts of any other tissues tested, kidney coming second, and then heart, brain, spleen, thymus, testes and skin, somewhat in the order named. The remaining tissues were weakly active as compared to lung, some of them showing very slight thromboplastic action. In considering a possible biologic significance of this unlike coagulative action of different tissues, Mills asks whether the marked potency of the lung may not represent a special protection in pulmonary diseases, in which extensive destruction of the tissue occurs. In the case of the kidney, likewise, a peculiarly effective protection against hemorrhage in a vital organ may be postulated. Whether or not lung tissue will offer a better starting point for the preparation of therapeutically available hemostatic extracts remains to be seen. Obviously, if the active principle is identified with certainty, its most advantageous preparation will not necessarily depend on the potency of any particular tissue, but rather on the most available source of the definite chemical compound concerned.

NEW INTESTINAL PARASITES: A PLEA FOR MORE CAREFUL FECAL EXAMINATIONS

The extensive examinations made on soldiers during the war, and previously on many hundreds of civilians as part of the modern attempts to eradicate hookworm infection, have emphasized the paucity of our information regarding the intestinal zooparasites of man. Tapeworms and roundworms have long been recognized; some species are, in fact, not easy to overlook, owing to their conspicuous size and characters. The systematic use of the microscope has, however, revealed unexpected numbers and numerous novelties in the nature of such parasitic invaders.

About a year ago Kofoed and White,⁴ working in the army laboratory at Metchnikoff, reported that a nematode (roundworm) ovum, apparently undescribed, had been found in 429 cases among approximately 140,000 soldiers examined. This is a characteristic illustration of what careful examination on a large scale may bring to light in clinical diagnosis. The ovum in question possessed a uniqueness in addition to its novelty, for it was said to be the largest ovum of intestinal worms encountered in human stools. Its dimensions averaged 95 by 40 microns, but the size was extraordinarily variable in different specimens. Kofoed and White were unable to identify the species, though they

3. Mills, C. A.: The Activity of Lung Extract as Compared to Extracts of Other Tissues, in Inducing Coagulation of the Blood, *J. Biol. Chem.* **40**: 425 (Dec.) 1919.

4. Kofoed, C. A., and White, A. W.: A New Nematode Infection of Man, *J. A. M. A.* **72**: 567 (Feb. 22) 1919.

1. Howell, W. H.: *Am. J. Physiol.* **31**: 1, 1912; The Coagulation of the Blood, Harvey Lectures, 1916-1917, p. 288.

regarded it as related to *Oxyuris vermicularis*, the well known pinworm, seatworm or mawworm.

This record has now been surpassed by the finding of the eggs and specimens of an oxyurid hitherto unreported for man.⁵ They came from a child living in the Philippine Islands. The ova are stated by Riley, who identified them at the University of Minnesota, to measure 125 by 40 microns. The worms, though resembling the genus to which the ordinary pinworm belongs, probably are of the species *Syphacia obvelata*.⁶ Along with them appeared fragments of the rat tapeworm of man, a cestode likely to be found quite common in the United States. Thus, Frey⁷ found this tapeworm not long ago in a third of the inmates of a Southern orphans' home, this incidence being exceeded only by that of hookworm infestation in the same group of 270 children.

These dwarf tapeworms are common to rodents, notably rats and mice. In man they are easily overlooked because of their small size, so that intensive routine examinations, such as hookworm tests require, alone afford a diagnosis. In the Philippine instance just recorded, a rodent tapeworm was found in a case in which the food of the child had evidently been contaminated by rats or mice. It is not improbable that these rodents also may have been responsible for the occurrence of the ova of the newly described species of roundworm. The circumstances related in the foregoing summary indicate the great importance of careful fecal examinations—an essential routine all too often entirely neglected.

"CHRISTIAN SCIENCE" AND SLOPPY THINKING

A New Jersey salesman, who claims to have been a member of the "Christian Science" faith for three years, was recently found guilty of manslaughter because he had permitted his 9-year-old daughter, who was suffering from diphtheria, to die without medical treatment. The little girl was given "treatment"—"absent" and otherwise—by a professional "Christian Science" practitioner. The man was fined \$1,000 and costs. The judge, in imposing sentence, is reported to have said:

In the light of present-day science, which is the result of many years of progressive experiment and demonstration, no one is justified in neglecting the use of such agencies as have been shown to be efficient in the treatment of malignant and contagious diseases, and this is especially true where one is charged with responsibility over the life of another, and particularly of a child of tender years, who has no option but to rely on the common sense and good judgment of its natural protector.

The verdict has brought to light, as such verdicts are likely to do, the loose thinking that characterizes

so many of the so-called intellectuals of today. Well-meaning people, who deny that they are followers of Mrs. Eddy, have written to the newspapers denouncing the verdict and declaring that it is little less than a crime that a man should be punished for following the dictates of his conscience. The main point stressed by such people seems to be that as children occasionally die of diphtheria under medical treatment, there is no reason for getting excited when a child dies under "Christian Science" treatment. The argument, of course, is fallacious. The efficacy of the modern scientific medical treatment of diphtheria is not a matter of theory, belief or conscience—it is a matter of fact. Its efficacy is as demonstrable as is the efficacy of the Westinghouse air brake. The parent or guardian who fails to give his child or ward the benefit of modern medical treatment for diphtheria becomes as culpable as a railroad would be if it failed to equip its passenger trains with air brakes. Sometimes, it is true, the air brake fails to avert a fatality; but that is not the fault of the air brake, nor is it any argument for its abolition.

If an adult in his own right mind wishes to be treated by "Christian Science" or any other unscientific methods, there can be no objection, provided the disease from which he is suffering may not, through such treatment, become a menace to the community. Children of tender years, however, should not be sacrificed to the distorted views of those who are supposed to be their protectors.

Religious beliefs should be respected and, in general, they are respected. Where, however, religious beliefs conflict with the general welfare, such beliefs must give way. Presumably, the Mormons were sincere in their belief in polygamy; that particular tenet of their religion, however, had to give way to the more enlightened belief of the rest of the community. The Dukhobors that migrated to Canada were undoubtedly sincere in their belief that they should go nude, and the practice of this belief was undoubtedly less of a menace to the community than are some of the bizarre views held by "Christian Scientists" regarding the cause and treatment of disease. Nevertheless, the Dukhobors had to put on clothes. It is conceivable that we might have transplanted to this country some of the religious beliefs of India, but it is doubtful whether public opinion in the United States would ever look with equanimity on Sutteeism, even though the widows might declare that being burned on the funeral pyres of their deceased husbands was a matter of their own personal belief and was none of the concern of the general public. Only a few weeks ago a man in Chicago shot his son with the avowed intention of killing the boy because he feared the lad was acquiring bad habits and he wished to save the boy's soul. We have not yet noticed any letters of indignation protesting against the man's arrest. Possibly this

is because he represents a minority. Should such beliefs ever reach the dignity of a religious cult with money and well-organized publicity machinery behind it, there would doubtless be found many to defend the killing of minors for the purpose of "saving" them.

Current Comment

THE STREPTOCOCCI COMMONLY FOUND IN MILK

Streptococci are associated by the bacteriologically trained mind with inflammation and suppuration and all the dangers that they may entail. Hence, when it was reported that the streptococci that cause garget or mastitis in cattle are found abundantly in the milk of infected cows, it was easy to speculate on the possible ills of mankind that might follow the drinking of raw milk. How to make the indispensable food, milk, safe is an important problem. As we cannot escape the ever-present bacteria of our environment, it is essential that their nature should be recognized. It has been realized for some time that not all micro-organisms are baneful; some are even beneficent. Let it be said clearly, also, that not all streptococci are virulent. For a number of years it has been customary to lay stress on cleanliness of both man and beast in the handling of milk for human consumption. There is no longer any doubt that attention to this factor will greatly reduce the microbial content, the keeping qualities, and in general the wholesomeness of market milk. But it may come as somewhat of a surprise to many that the external, environmental factors related to the cow are by no means always the most menacing to the bacteriologic purity of milk. Man, the carrier of harmful species, is of course a constant source of danger; but the "dirt" that accumulates mechanically about the animal is far less threatening. According to the most recent observations of Jones¹ at the Rockefeller Institute Laboratories at Princeton, neither the fecal nor the skin streptococci of cows have been isolated from unpasteurized bottled milk of good grade with any great frequency, despite the fact that nonhemolytic types of these micro-organisms can be found in the vagina, saliva, skin and feces of the cattle. The principal source of the streptococci in milk, according to Jones, is the cow's udder. Most of the streptococci agree in character with mastitis streptococci, a fact that may now be regarded as definitely established. Although these have been observed in the milk marketed from a large herd during the last two years, diseases traceable to this milk supply have never been reported. Jones therefore believes that this evidence points to the low pathogenicity for man of the streptococci, particularly udder types, derived from the cattle and found in their milk. If this is established, such streptococci may be excluded as the source of severe epidemics of milk-borne sore throat. For this, human agencies must still be held responsible.

THE DEADLY MOTOR CAR

In an analysis of the accidents occurring in St. Louis during March, 1920, the National Safety Council indicates that there were eleven fatalities and 187 persons injured in 494 automobile accidents. This, it must be noted, was in one month and in a city of less than a million population. The total number of accidents of all kinds was 791, so that the automobile accidents constituted almost two thirds of the total. The property damage was estimated at \$39,500. The causes were not determined in 190 instances; skidding was responsible for ninety-one; careless driving for 205, and careless walking for twenty-seven. Quite a few of the accidents are ascribable to the carelessness of the motorist in giving the signal of his intent to turn, to pass, to stop, to back or to drive out from the curb. A few accidents were due to the glare of undimmed headlights. The great majority of all traffic accidents and fatalities are due to "carelessness." It is a safety aphorism that carelessness can be overcome only by education.

THE ACQUIRED TOLERANCE FOR MORPHIN

The explanations of those forms of idiosyncrasy which consist in failure of a person to react to the ordinary dose of a drug have been both varied and inconclusive. The instance technically designated as acquired tolerance represents a greatly decreased susceptibility to a drug as the dose is repeated. The person becomes readjusted to a new agency, whether it be alcohol, nicotine, arsenic or an opium alkaloid. Thus are drug habits formed. How does an originally sensitive and responsive organism acquire an immunity whereby it may withstand a previously toxic and sometimes ordinarily fatal dose? Apparently in some cases the tissues become adapted to the drug so that it no longer reacts as a foreign substance. Sometimes the intestinal absorption of the compound may decrease with increasing use by oral administration. This explanation has been offered for the acquired tolerance for arsenic, it being reported that frequently when large amounts are becoming tolerated by mouth, much smaller doses given subcutaneously may be toxic. Again, the defenses of the organism may become strengthened, so that a given compound is more readily destroyed by oxidation in the body. In some cases, antitoxic agencies of a chemical nature may actually come into prominence. Whether any of these possible mechanisms explanatory of tolerance are specific for individual drugs, or whether they represent more general biologic responses which might meet a variety of exigencies, is not so clear. It has been reported that the prolonged use of one drug may establish tolerance for others of the same class. Thus, it is said that chronic alcohol drunkards are more resistant than ordinary persons to the action of chloroform. If this is true, the explanation may lie in the fact that the chemically related chloroform and alcohol induce the same changes in the protoplasm. Precisely how tolerance to morphin is acquired is not yet clear. Faust¹ believed that whereas normal persons excrete

1. Faust, E. S.: Ueber die Ursache der Gewöhnung an Morphin, *Arch. f. exper. Path. u. Pharmacol.* 44: 217.

this alkaloid practically unchanged, showing that it circulates as such in the body, in those having a "habit" for morphin it is partially destroyed. This hypothesis of an increased destruction of the drug in tolerance has not been tenable in the light of subsequent researches.² Biberfeld³ has demonstrated, however, that the tolerance to morphin is quite specific. In animals "immunized" to this narcotic, ordinary doses of a drug even so closely related as is diacetylmorphin (heroin) are unquestionably potent. Furthermore, according to Biberfeld's studies in the Pharmacologic Institute at Breslau, marked tolerance to morphin does not protect against the soporific barbitol (veronal), nor against scopolamin or cocain. It has been asserted from time to time that the blood of persons exhibiting high tolerance contains protective, antagonistic or "immune" substances which are developed with the immunity to morphin. Carefully conducted investigations with the serum of tolerant animals have, however, thus far failed to afford any real substantiation of these assertions.

RESPIRATORY DISEASE TRANSMISSION BY INANIMATE OBJECTS

Cumming⁴ has suggested, in discussing the transmission of influenza and influenzal pneumonia, that the hands are important factors in the conveyance of germs to healthy persons, and furthermore that hand-to-mouth infection will account for the major part of this transmission. In these studies the methods of washing army mess-kits were particularly concerned, as the wash water served as a means for the contamination of the hands in the groups showing high influenza rates. In a later article,⁵ Cumming reports the results of a study of pneumonia in institutions, in some of which eating utensils were washed by hand and in others by machine washers. In the first group the pneumonia rate was much higher than in the second group. Still more recently the same investigator⁶ has laid primary emphasis on tableware, particularly spoons, forks and knives, as a means of transmitting tuberculosis. This point of view is confirmed by deaths of guinea-pigs from tuberculosis in 25 per cent. of instances after injections of sediment from water in which spoons used by tuberculous patients had been rinsed after washing. In accepting these findings, however, it should be remembered that in intelligent households silverware is usually both washed and rinsed before being used again. It would be interesting to know the influence of the combination of these operations on freeing spoons from tubercle bacilli. The work of Cumming focuses the attention of sanitarians on other means of conveying germs of respiratory diseases than by droplet infection directly from mouth to mouth. More data are needed to show that

these means are really the major ones. It is probably true that the inanimate objects and hands are capable of conveying disease germs as well as are the infectious droplets, and it is possible that too little attention has been given to them.

IN THE COURSE OF THE DAY'S WORK

An interesting though not unique case is described in a recent bulletin sent out by the Federal Board for Vocational Education. Among the blinded ex-service men was a negro who seemed to be blind in both eyes. Neither eye could perceive five fingers at any distance. He had faint light perception and there was hope for sight restoration in one eye. The man was about to be assigned to a workshop for the blind when a physician managed to persuade him that he was not blind. The report of the case reads:

He was suffering from psychoneurosis hysteria giving rise to marked blepharospasm and photophobia and amaurosis. All physical findings negative. Treatment by suggestion completely cleared up all symptoms and I discharged this man cured.

This case is not referred to because it is unique in medicine for, as physicians know, it is not. Had the man regained his sight, however, while under "Christian Science" treatment or while having his vertebrae pushed by a chiropractor, what a to-do would have been made of it. The case would have become a classic in the annals of the cult. As it is, the incident would never have reached the public eye had it not been for the bulletin of the vocational educational board.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DELAWARE

Child Welfare Activities.—On request of the Delaware Reconstruction Commission, an officer of the United States Public Health Service has been assigned to duty in Wilmington in the office of the director of this commission as medical director of the child hygiene activities. He has under his supervision a number of children's clinics and health centers already established and will advise and assist in the establishment of others. In addition, he will exercise general supervision of medical inspection of schoolchildren about to be undertaken in the state in cooperation with a number of authorized and volunteer agencies.

DISTRICT OF COLUMBIA

Personal.—Dr. Van H. Manning, director of the Bureau of Mines, Department of the Interior, has tendered his resignation, effective June 1. Dr. Manning is leaving the government service to accept the position of director of research with the recently organized American Petroleum Institute. —Dr. Ross McC. Chapman, for more than four years assistant superintendent of St. Elizabeth's Hospital, Anacostia, has been appointed medical superintendent of the Sheppard and Enoch Pratt Hospital, Towson, Md.

Survey of Delinquents.—On request of the judge of the juvenile court of the District of Columbia, officers have been assigned to the probation office for the purpose of making physical and mental examinations of juvenile delinquents and supplying the court with information relating to the physical and mental status of such delinquents, to be taken

5. Cumming, J. G.: Am. J. Pub. Health 9: 849 (Nov.) 1919.

6. Cumming, J. G.: Can the Tuberculosis Transmission Rate Be Reduced? J. A. M. A. 74: 1072 (April 17) 1920.

into consideration in arriving at judicial decisions. Each child coming before the court will be subjected to an intensive physical and mental examination. These will be accompanied by careful medical-social follow-up work.

ILLINOIS

Personal.—Dr. Frank P. Norbury, Springfield, has been appointed neuropsychiatrist to the Wabash Railway System.—Dr. Arthur F. Stotts, Galesburg, was shot by the husband of a patient, May 8, and is under treatment at the Cottage Hospital, Galesburg.

The Venereal Disease Menace.—A special discussion arranged by the Illinois Social Hygiene League was held at the Rockford Theater, Rockford, May 18. Moving pictures of venereal disease treatment were shown, and described by Dr. Alec N. Thomson, Brooklyn; Assistant Surgeon-General Claude C. Pierce, U. S. P. H. S., spoke on "Venereal Disease and the Local Practitioner," Dr. William L. Baum, Chicago, on "Local Phases of the Venereal Disease Menace," and Robert H. Gault, professor of criminology in Northwestern University, and president of the league, detailed the plans of the Illinois Social Hygiene League.

Organized Chiropractors Checked.—A report from the director of registration and education of Illinois states that twenty-five chiropractors have been enjoined by the circuit court of Rock Island County from treating human ailments without state licenses. These twenty-five chiropractors are members of Class "A" of the Universal Chiropractors' Association with headquarters at Davenport, Iowa. The Class "A" members of this association pay a membership fee and quarterly dues. In consideration of the payments, the association pays all fines assessed against them by the courts in Illinois for practicing without licenses. It also pays the fees of attorneys for defending them. When a chiropractor is fined in the courts, he is advised by the officers of the association to continue in his unlawful practice. The circuit court of Rock Island has temporarily enjoined these chiropractors from treating human ailments without licenses and has also enjoined them from carrying out the terms of their unlawful agreement with one another. They are enjoined from contributing to and paying, or paying any part of, the fines and costs and also the expenses and attorney fees that are assessed, or the expenses incurred by any person other than the one prosecuted in an individual case. B. J. Palmer, head of the Palmer School of Chiropractic at Davenport and secretary of the Universal Chiropractors' Association, is enjoined from paying the fines, costs, expenses and attorney fees of Class "A" members in Illinois. Thomas M. Morris and Fred Hartwell of LaCrosse, Wis., attorneys for the association, are enjoined from representing in the Illinois courts any of the members of the Universal Chiropractors' Association. The chiropractors who are enjoined are: Charles J. Brutus, Jesse Newman, Dora K. Yunker and F. W. Linsenmeyer, Champaign, Champaign County; R. E. Davenport, Chicago, Cook County; B. A. Clayton, Mrs. E. E. Clayton and A. H. Morrow, Kewanee, Henry County; Lena M. Warrick and T. L. Warrick, Ottawa, LaSalle County; Mary E. S. Fulleton Tiska and A. W. Tiska, Highland, Madison County; J. C. Underwood, Bloomington, McLean County; Philip H. Griggs, Jacksonville, Morgan County; W. J. Buchanan, Riley E. Bowman, E. T. Henry and S. F. Stewart, Peoria, Peoria County; Emma Calvin, Monticello, Piatt County; H. N. Mettler and Emma S. Rooks, Rock Island, and I. H. Beckholt, East Moline, Rock Island County; R. W. Peerman, Eldorado, Saline County; Elizabeth Goss, Delavan, Tazewell County, and J. L. Hubbard, Minonk, Woodford County. The writ in the injunction proceedings was signed by Attorney-General Brundage, State's Attorney Bell of Rock Island County, and Francis W. Shepardson, director of registration and education. The bill asks that other Class "A" members of the association who have conspired and confederated may be made parties defendant to the bill and bound by the order of the court as soon as their names are ascertained.

Chicago

Personal.—Dr. C. Hubart Lovewell and Elmer E. Simpson were overcome by fumes from a gas heater while attempting to revive patients who had been overcome by gas.—Dr. Charles Louis Mix has accepted the position as head of the department of medicine of Loyola University School of Medicine.

Medical School Recognized.—A letter from the president of the Bureau of Medical Education and Licensure of Penn-

sylvania states that on April 21 the bureau voted to include Loyola University School of Medicine on its approved list, not only admitting its graduates to examinations but also receiving them through reciprocity.

INDIANA

Smallpox Epidemic.—An epidemic of smallpox is said to be prevalent in the Calumet region, Gary having forty-five cases and Hammond, fifty-two, several cases being reported also in Whiting, East Chicago and Indiana Harbor.

Vote for County Hospital.—At the recent election in Adams County, held in Decatur, to decide on the proposition to build a new hospital for Adams County to cost \$100,000, 1,601 votes were cast in favor of the hospital and 1,347 against it.

Hospital Items.—The physicians of Shelbyville and Shelby County have recently formed the Shelby County Hospital Association. The association has purchased a site in Shelbyville where it proposes to erect a hospital.—Public subscriptions amounting to \$105,000 have been received by the committee in charge of buying the Home Hospital at Muncie with a view to transferring it to a board of governors, who will operate it as a public hospital.—The City Hospital at Madison was recently combined with the King's Daughter's Hospital of that place.

IOWA

Personal.—Dr. Dallas L. Scarborough, Grand Junction, fell recently and fractured his hip. He is under treatment in a hospital in Iowa City.

County Society Reorganized.—Fremont County Medical Society which has lain dormant during the World War was reorganized, April 28, at Sydney. Dr. Brownlow B. Miller, Tabor, was elected president; Dr. Ralph S. Lovelady, Sydney, vice president, and Dr. Ambrose E. Wanamaker, Hamburg, secretary.

New State Officers.—At the annual meeting of the Iowa State Medical Society held in Des Moines, May 12 to 14, under the presidency of Dr. William L. Allen, Davenport, the following officers were elected: president, Dr. Donald Macrae, Jr., Council Bluffs; president-elect, Dr. Alanson M. Pond, Dubuque; vice president, Dr. Campbell P. Howard, Iowa City; secretary, Dr. Thomas B. Throckmorton, Des Moines (reelected); treasurer, Dr. Thomas F. Duhigg, Des Moines (reelected), and editor, Dr. David S. Fairchild, Clinton (reelected).

MARYLAND

Hospital to Open.—The Volunteers of America Hospital will be open for inspection, May 24. The hospital will not be ready to receive patients for about thirty days. The institution contains forty beds, and was built and equipped at a cost of \$40,000.

Gift to Phipps Clinic.—A gift of \$100,000 has been made to the Phipps Psychiatric Clinic, Johns Hopkins Hospital, by Henry Phipps of New York, founder of the clinic. This sum is to be a nucleus of a permanent endowment for the clinic. When the clinic was built, Mr. Phipps provided a maintenance fund for a period of ten years. Seven of the ten have already passed, so that this gift was received with great gratification by the hospital authorities. It will require the interest on \$1,200,000 to maintain the hospital on its present basis, according to the hospital authorities, and interest on a fund of \$2,000,000 will be needed to make full use of its laboratories and to provide for research work.

MASSACHUSETTS

Hospital Reopened.—St. John's Hospital, Lowell, with its new additions and alterations which have been in course of construction for the last two years at an expense of about \$600,000 was formally reopened, May 12.

State Society to Meet.—The one hundred and thirty-ninth annual meeting of the Massachusetts Medical Society will be held, June 8 and 9, at the Boston Medical Library, under the presidency of Dr. Alfred Worcester, Waltham. The Shattuck Lecture will be delivered on the first evening by Asst. Surg.-Gen. Allan J. McLaughlin, U. S. P. H. S., Washington, D. C., on "Influenza"; the annual discourse on Wednesday noon, by Dr. Hugh Cabot, professor of surgery at the University of Michigan, Ann Arbor, on "Health Insurance, State Medicine or What?" The annual dinner will be served at the American House, Boston, on Wednesday afternoon.

Personal.—Dr. Stanley H. Osborn, Boston, epidemiologist of the Massachusetts Department of Public Health, has resigned to accept the directorship in the Bureau of Preventable Diseases in the Connecticut State Department of Health, Hartford.—Dr. McIver Woody, Boston, has been appointed dean of the Medical Department of the University of Tennessee, Memphis.—Dr. John H. Wyman, Quincy, has been reappointed associate medical examiner (coroner) for the Seventh Norfolk District.—Dr. James J. Goodwin, Clinton, has been appointed associate examiner (coroner) for the Fourth Worcester District.—Dr. George L. Tobey, Clinton, has been appointed medical examiner (coroner) for the Fourth Worcester District.—Dr. Randolph C. Hurd, Newburyport, has been appointed associate medical examiner (coroner) for the Third Essex District.—Dr. William T. Sedgwick, Boston, has sailed for England as the first exchange professor of public health. He will serve for a time as a member of the faculties of the universities of Cambridge and Leeds. Dr. Sedgwick has been elected a fellow of the Royal Institute of Public Health.

MICHIGAN

Hospital Commission Appointed.—A hospital commission has been appointed to have charge of the expenditure of \$60,000, which has been raised by bond issue for an emergency hospital at Port Huron.

Personal.—Dr. Christopher G. Parnall, medical superintendent and director of the University Hospital, Ann Arbor, has been appointed a member of the Rockefeller Commission for the Study of Nursing Education.

Cooperation of Druggists in Venereal Disease Campaigns.—Much has been accomplished by the Michigan Department of Health in obtaining cooperation of druggists in conducting a venereal disease campaign. The venereal disease law, as passed by the Michigan legislature of 1919, required druggists to report venereal disease prescriptions when marked as such, to the Michigan Department of Health and also to discontinue dispensing medicine to venereal disease patients. During the first six months, 1,100 druggists reported prescriptions; 1,224 physicians wrote prescriptions; of the 1,721 estimated druggists in the state, 63.91 per cent. reported; 14,823 prescriptions were reported, and 10,055 cases of venereal disease were reported by physicians.

MISSOURI

Boylston Prize Awarded.—The Boylston Prize of \$300 has been awarded to Stuart Mudd, Samuel B. Grant and Alfred Goldman, fourth year students at Washington University Medical School, St. Louis, for their essay on "The Effect of Chilling on the Membrane of the Throat and Tonsil."

New Hospital at Westplains.—Dr. Robert E. Hogan, Westplains, has completed and opened for service a hospital at Westplains under the name of Christa Hogan Hospital, in memory of his mother. The building is of brick, has twenty-one rooms and is at the service of all reputable practitioners.

Personal.—Dr. Moses B. Harutun, Joplin, has been elected commissioner of health and has appointed Dr. John A. Chenoweth as city physician.—Dr. Kate C. Spain, St. Louis, was severely injured, April 22, by being struck by an automobile while crossing a street.—Dr. Frank N. Wilson, St. Louis, has been appointed one of the American editors of *Hcart*.—Dr. Frederick Hagler, St. Louis, has been appointed chief surgeon of the Stevens-Duryea Corporation, Chicopee Falls, Mass.

Public Health Service Conducts Child Welfare Experiment in Missouri.—At the request of the state health authorities, an extensive field investigation and demonstration in child hygiene activities is being made by the public health service. In addition to a staff of health officers from this service, seven women physicians and six women nurses, in addition to a full complement of women field investigators, have been appointed and are in the field. Efforts are being made to provide better supervision of expectant mothers and to provide facilities whereby mothers can secure medical advice and assistance in the care of their babies. In all these activities, the aim is to establish in the Missouri Board of Health a model bureau of child hygiene for dealing with the health of mothers and children. The work is being so planned and conducted that when the present survey and demonstration are completed a permanent organization will

be left behind, supported entirely by the communities themselves.

NEW YORK

Dinner to Dr. Mandlebaum.—A dinner was tendered on May 8, at the Hotel Biltmore by the president and former members of the laboratory staff of Mount Sinai Hospital in honor of the twenty-fifth anniversary of Dr. Frederick S. Mandlebaum's appointment as pathologist to the institution. Among the guests were the president and the executive officers of the hospital.

Hearing on Chiropractor Bill.—A hearing on the bill providing for state licensing of chiropractors was held before Governor Smith, May 13. Among those who opposed the bill were Dr. Augustus Downing, deputy state commissioner of education, and Dr. Hermann M. Biggs, state health commissioner, representatives of the state health officers' association, the state charities aid association, the New York City Health Department and the New York Academy of Medicine.

Joint Clinics to Be Held.—The Committee on Joint Mental Clinics is planning to hold a large joint clinic during a six-day period for the purpose of furnishing expert diagnosis in the cases of patients brought to it. The clinic will cover an entire county after a survey has been made by public health nurses. The cases examined will include children's diseases, venereal diseases, tuberculosis, cancer, mental diseases and mental defectives, and although the work will be largely diagnostic, a follow-up system will be organized.

Public Tuberculosis Meeting.—The first public meeting of the New York Tuberculosis Association was held May 18, in the New York Academy of Medicine, when the subject of discussion was "How the New York Tuberculosis Associations Plan to Restore the Consumptive to Industry." Dr. James Alexander Miller presided, and a brief report was made of the accomplishments of the association during its first three months. The topic was discussed under four heads: the plan; occupation in treatment and convalescence; methods of occupational and vocational training, and after-care and the association's workshop.

Dentists Endorse Health Center Plan.—The New York Dental Society, at its annual meeting, unanimously adopted a resolution approving the provisions of the health center bill endorsed in the last legislature and placing special stress on the great need for proper care of the mouth and teeth of the rural population and for instructions in the disastrous physical results of neglecting to provide such measures. Ninety per cent. of children, 7 years of age, are suffering, it is estimated, from mouth defects requiring correction, and the Life Extension Institute, in 125,000 examinations, found that 14 per cent. of those examined had marked infections of the teeth and gums. The resolution provided for the appointment of a committee of the state dental society to cooperate with all other organizations concerned with or interested in public health, with a view to securing favorable action on the bill at the next session of the legislature.

New York City

Milk and Child Exposition.—The New York City Department of Health announces that it will hold a milk and child exposition in Grand Central Palace beginning on May 17, designed to educate the public as to the value of milk for children.

Campaign Against Cancer.—The American Society for the Control of Cancer held a special meeting at the New York Academy of Medicine, May 13, at which Dr. Harvey Gaylord of Buffalo spoke on the "Less Familiar Problems of Cancer," and Dr. Howard Lilienthal on "Cancer from the Standpoint of the Clinical Surgeon." This meeting was the opening event of the campaign against cancer that is to be carried on in this city during the last week in May, when a number of lay meetings will be held throughout the city. Dr. Frederick T. Van Buren is director of the campaign. Twenty-five physicians have agreed to deliver addresses at meetings during the week.

United Hospital Fund Distributed.—The United Hospital Fund has completed the distribution of \$850,000 among the forty-four nonmunicipal hospitals of the city. Of the amount, \$400,000 was distributed among nineteen general hospitals in February, after the campaign to secure \$1,000,000 had been closed. The remaining \$425,000 has been distributed among ten special hospitals, nine women's and children's hospitals and six homes for chronics and convalescents. The daily per capita cost of patients in the forty-six united hospitals in

1914 was \$2.02; four years later it was \$3.20. In 1911, 39 per cent. of the patients were listed as free patients, while in 1918 only 23 per cent. were free patients.

Personal.—Dr. Louise Pearce of the Rockefeller Institute for Medical Research sailed for England and Belgium en route to the Belgian Congo to study the chemotherapy of African sleeping sickness.—Dr. Royall H. Willis, Sea Gate, retired, formerly assistant director of the bureau of child hygiene of the department of health, was recently presented with a signet ring by the members of the bureau as a token of their appreciation of his courtesy and consideration during his service of over twenty years.—Dr. Otto V. Huffman, Brooklyn, dean of the Long Island College Hospital, has resigned and has been appointed a member of the faculty of internal medicine in the New York Post-Graduate School and Hospital.—Dr. Charles Gordon Heyd has been appointed professor of surgery at the New York Post-Graduate School and Hospital.

OREGON

Cooperates in Mental Hygiene Survey.—The University Extension Department of the University of Oregon, with the approval of the state health officer, invited the United States Public Health Service to cooperate with the university in making a survey of the extent of the delinquency, dependency and feeble-mindedness problems of the state from the standpoint of mental hygiene. These investigations were authorized at the last meeting of the state legislature. This survey is made by the communities themselves, under expert direction, and when necessary with the active participation of the expert. Under the constitution, all new legislation involving appropriations must be submitted to the people for a referendum vote; hence the survey now being made may be counted on to constitute an important measure for educating the people in all lines of social hygiene, including mental, physical and child hygiene.

PENNSYLVANIA

Personal.—Dr. John French Kerr, Connellsville, has volunteered his services as a medical missionary in Africa under the Board of Foreign Missions of the United Presbyterian Church.

Compulsory Health Insurance.—At the meeting of the Pittsburgh Public Health Nursing Association, to be held May 27, John B. Andrews, Ph.D., secretary of the American Association of Labor Legislation, will speak on "Compulsory Health Insurance."

Philadelphia

Medical Club to Give Reception.—The Medical Club of Philadelphia has issued invitations to a reception to be given in honor of Dwight W. Morrow, May 28, at the Bellevue-Stratford.

Californian Speaks Before College.—At the stated meeting of the College of Physicians of Philadelphia, May 5, Dr. George H. Whipple, professor of research medicine in the University of California, read a paper entitled "Studies on Blood Regeneration in Anemia."

The Gross Prize.—The Samuel D. Gross prize of the Philadelphia Academy of Surgery for 1920, amounting to \$1,500, has been awarded to Dr. Everts A. Graham of Washington University Medical School, St. Louis, for his essay entitled "Some Fundamental Considerations in the Treatment of Empyema Thoracis."

WISCONSIN

Personal.—Dr. Frank M. McGauley has resigned as city physician and health officer of Fond du Lac, and has been succeeded by Dr. Ned J. Malloy, Fond du Lac.

Hospital Burns.—The Egeland Hospital, Sturgeon Bay, was entirely destroyed by fire recently. Dr. Egeland has secured an option on the Joseph Richmond Building, Sturgeon Bay, and will remodel it for use as a hospital.

CANADA

New Salvation Army Hospital.—A new maternity hospital is to be built in Ottawa, Ont., by the Salvation Army at a cost of \$125,000. It will be completed and ready for occupation by the end of November.

Academy Election.—Dr. Jabez H. Elliott has been elected president of the Academy of Medicine, Toronto; Dr. Robert T. Noble, vice president; Dr. J. Herbert McConnell, treasurer

(reelected), and Dr. Frederick C. Harrison, secretary (reelected).

Personal.—Dr. Frank Gray has arrived in Montreal from England.—Dr. Margaret Parks, St. John, has been appointed medical inspector of New Brunswick under the Dominion Government. She will have charge of inspecting immigrants at the port of St. John.

Hospital Burns.—Fire caused by an overheated furnace destroyed the Essex County Tuberculosis Sanatorium, Union-on-the-Lake, forty miles south of Windsor, April 29. The forty-five patients escaped without injury and were sheltered in neighboring homes pending their removal to the Hotel Dieu, Windsor. The loss is estimated at \$100,000.

University News.—Lieut.-Gen. Sir Arthur Currie, inspector-general of the Canadian militia, and commander of the Canadian forces in France, has been given the degree of Doctor of Laws by McGill University, Montreal, and appointed president of that institution in succession to Sir Auckland C. Geddes, Montreal. Before participating in the great war, General Currie was in business in Vancouver. He held no university degree, but had taught school for six years. Not being a university man, the appointment of the general will be watched with interest by educators.

Medical Associations to Meet.—The annual meeting of the Canadian Medical Association will be held in Vancouver, June 22 to 25. The address in medicine will be delivered by Dr. Charles Lyman Greene, St. Paul, and the address in surgery by Dr. Edward Archibald, Montreal, on "Surgical Treatment of Ulcerated Intestinal Tuberculosis as Occurring Chiefly in Pulmonary Tuberculosis."—The annual meeting of the Canadian Public Health Association will be at Vancouver, June 21 to 23, under the presidency of Dr. Henry E. Young, Victoria, B. C.—The fortieth annual meeting of the Ontario Medical Association will be held in Toronto, May 25 to 28.

Health Board Given Additional Power.—The Provincial Board of Health of Ontario by an act of the legislature will be created a "body corporate." This results as an aftermath of the recent smallpox epidemic and the compulsory vaccination complexity. As the courts recently declined to uphold the compulsory vaccination order of the Ontario Board of Health, the officials of the board sought proper legislative authority to enforce the vaccination act should conditions again arise demanding its enforcement. It has been held by these selfsame officials that the Board of Health of Toronto, being a corporate body, had this authority, but failed to exercise it, and left the onus of doing so on the Ontario Board of Health.

Tuberculosis in Canada.—Dr. Charles D. Parfitt, Gravenhurst, before the special committee on pensions in Ottawa, has stated that during the great war 35,684 Canadian soldiers were killed in action in five years, while the number of deaths from tuberculosis in Canada during five years was 42,920. There were 8,508 cases of tuberculosis in the Canadian Expeditionary Forces during five and three-quarters years up to April 30, 1920. In the case of men discharged with the disease apparently arrested, the most critical time was the second year after the discharge when a man becomes less careful. Mortality was heaviest four years after discharge, and approached normal in seven years. He maintained that the maximum pension should be granted temporarily and should be subject to frequent revision as needed.

GENERAL

New Hospital Magazine.—The first copy of *Hospital Progress* has just appeared, this being the official magazine of the Catholic Hospital Association of the United States and Canada.

Public Health Meeting Postponed.—The date of the annual meeting of the American Public Health Association at San Francisco has been changed from August 30 to September 13 to 17. The change was necessitated by the state election which is set for August 30.

Gorgas and Noble Sail for Africa.—Last week Gen. W. C. Gorgas left for England, where he is to receive an honorary degree. He was accompanied by Brig-Gen. Robert E. Noble, who is on a six months' leave of absence. They will proceed to West Africa to study what is alleged to be an outbreak of yellow fever in that district.

Red Cross Scholarships.—Ten scholarships in public health nursing of \$1,000 each are being offered by the League of Red Cross Societies to the Red Cross membership of stricken

countries or to nations with inefficient Red Cross organizations. The course of study will be carried out at the Kings College, Woman's Department, University of London, and will begin in October. The traveling expenses to London and return will be provided for holders of the scholarships.

Medical Women Elect Officers.—At the annual meeting of the Medical Women's National Association held in New Orleans, April 26 and 27, the following officers were elected: president, Dr. Mary Elizabeth Bass, New Orleans; vice presidents, Drs. Grace W. Kimball, Poughkeepsie, N. Y., M. Louise Hurrell, Rochester, N. Y., and Helena T. Rat-terman, Cincinnati; recording secretary-treasurer, Dr. L. Rose H. Gantt, Spartanburg, S. C., and corresponding secretary, Dr. Isabelle T. Smart, New York.

Baptists to Build Hospitals.—Authority to build a \$1,500,000 hospital in New Orleans was unanimously approved by the Southern Baptist Convention held at Washington, D. C. In presenting the report of the committee on hospitals to the convention, Dr. F. S. Groner of Texas declared that Baptists of the South are endeavoring to provide for adequate hospital facilities in various southern states. It is planned to erect Baptist hospitals in other cities. This plan includes one at Louisville, Ky., Lynchburg, Va., and one each in Alabama and North Carolina.

Civil Service Examinations.—The United States Civil Service Commission announces an open competitive examination for positions in the Indian Service; acting assistant surgeon, Public Health Service; surgeon in the coast and geodetic survey, and positions requiring similar qualifications, at salaries varying from \$1,000 to \$3,000 a year, for which applications will be received at any time. Examinations will be held, July 7 and September 8, for physician, Panama Canal Service, with an entrance salary of \$225 a month, with promotion to \$340 or more; and June 22, for bacteriologist, St. Elizabeth's Hospital, Washington, D. C., with a salary of \$2,500 a year.

Health Program of National Education Association.—At the annual meeting of the National Education Association to be held in Salt Lake City, July 5 to 9, inclusive, the evening session of July 7 is to be devoted to health education. The subject will be discussed by Prof. Thomas D. Wood of Columbia College, New York City; Sallie Lucas Jean, director of child health organization, New York City; E. G. Gowans, state health inspector, Salt Lake City; A. A. Slode, director of health association, Cheyenne, Wyo.; Margaret S. McNaught, commission of elementary education, Sacramento, Calif., and Catherine D. Blake, principal of Public School No. 6, Manhattan, N. Y.

Report on Coal-Tar Products by Alien Property Custodian.—Prior to the World War practically no medicines were manufactured in America from coal-tar products. This is shown in the report of the Alien Property Custodian which contains a chapter on how Germany dominated the American chemical and dyestuff industry. The report says in part:

"In medicinals very little real American manufacture existed. A few of the coal-tar pharmaceutical products were produced by two American houses in St. Louis, the Mallinckrodt Chemical Works and the Monsanto Chemical Works. The enormous dispensing and distributing business of such firms as Parke, Davis & Co., Lilly & Co., and Powers-Weightman-Rosengarten Co. successful and efficient as it was beyond comparison with similar business in any other country, seems to have involved very little real manufacture, and the materials used were largely imported. There seems to have been but little, if any German interests in this branch of the industry, except among small brokers and dealers."

Public Health Service Experiments on Milk Powders.—Since August last, the United States Public Health Service, cooperating with the Boston Baby Hygiene Association, Department of Pediatrics of the Massachusetts General Hospital and Dr. Milton J. Rosenau of the Department of Preventive Medicine in Harvard University, has been engaged in experiments to demonstrate the usability of dry milk powders. The experiments are to continue until the end of the present fiscal year, July 1, at which time a report on the work is to be published. In a preliminary statement it is said that the investigators have established the usability of such milk and that it is "unquestionably beneficial." It is to be utilized particularly for supplying all babies with milk in tropical and semitropical countries.

Nurses Elect Officers.—At the annual meeting of the American Nurses Association held last month in Atlanta, Ga., the following officers were reelected: president, Clara D. Noyes, Washington, D. C.; vice presidents, Susan D. Frances, Philadelphia, and Sarah D. Sly, Birmingham, Mich.; secretary, Katherine DeWitt, Rochester, N. Y., and

treasurer, Mrs. C. V. Twiss, New York City.—At the meeting of the National Organization for Public Health Nursing the following officers were elected: Edna Foley, Chicago, president; Elizabeth G. Fox, Washington, D. C., and Jessie Marriner, Montgomery, Ala., vice presidents, and Olive Chapman, Denver, secretary.—The National League for Nursing Education has elected the following officers: president, Anna C. Jamme, San Francisco; vice presidents, Louise M. Powell, Minneapolis, and Ida M. Stewart, New York City; secretary, Alice M. Flash, and treasurer, Bena M. Henderson.

Association of Medical Museums.—The thirteenth annual meeting of the American and Canadian Section of the International Association of Medical Museums was held at Cornell University Medical College, New York City, April 1, under the presidency of Dr. Oskar Klotz, Pittsburgh. The following officers were elected: president, W. M. Late Coplin, Philadelphia; vice presidents, Drs. James Ewing, New York City; Howard T. Karsner, Cleveland, and Harold E. Robertson, Minneapolis; councilors, Drs. Aldred S. Warthin, Ann Arbor, Mich.; Oskar Klotz, Pittsburgh; Robert A. Lambert, New York City; C. S. Silvester, Washington, D. C.; William G. MacCallum, Baltimore, and Lawrence J. Rhea, Montreal; secretary-treasurer, Maude E. S. Abbott, Montreal, reelected, and assistant secretaries, Louis Gross, Montreal, and Harry Goldblatt, Cleveland. The annual exhibition of the society of materials illustrating papers on the program of the association and the Association of Pathologists and Bacteriologists was held at Cornell University April 1 and 2.

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Vincent's Home and Maternity Hospital, Philadelphia, \$5,000 by the will of James B. Rodgers.

College of the City of New York, \$7,500 for a medical preparatory fellowship; Woman's Hospital, New York City, Hospital in India of the Dutch Reformed Church of New York, each \$5,000; St. Luke's Hospital, New York, for a free bed for consumptives, \$5,000, and Society of Widows and Orphans of Army Men, \$1,000 by the will of Miss Anna M. Sandham.

Biologic Institute, Lyons, France, a donation of 100,000 francs, the interest to be used to permit one student of the University of Lyons to devote his time to laboratory work on communicable diseases, by Mr. Douglas Flattery.

St. Luke's Hospital, Davenport, Ia., \$10,000 by the will of Judge Nathaniel French.

Lynchburg, Va., Home and Retreat, a gift of \$60,000 by the family of James P. Gilliam as a memorial to Mr. Gilliam.

Industrial Home Association for Destitute Children, Trenton, N. J., \$2,000, and Mercer Hospital, Trenton, \$1,000, after the death of his wife, by the will of Wesley Creveling.

Toronto Free Hospital for Consumptives, Muskoka Free Hospital for Consumptives and Queen Mary's Hospital for Consumptives, Weston, Ont., each \$1,000 by the will of Mrs. Featherstonbaugh, Toronto.

French Hospital, Montreal, \$6,000 the result of Tag Day, May 5.

The United States Pharmacopeial Convention.—The Tenth Decennial Pharmacopeial Convention was held in Washington, D. C., May 11 and 12, under the presidency of Dr. Harvey W. Wiley. Dr. Wiley, in his presidential address emphasized the importance of maintaining a judicial frame of mind in compiling the new edition of the Pharmacopeia, and insisted that a conscientious observation must be given to the principle in law which forbids a judge in a court of equity to permit personal advantage to influence the actions of the court. He called attention to the importance of the Pharmacopeia as a book of standards and its value to the public. Dr. Reed Hunt, Boston, was elected president for the next decennium, and Dr. Lyman F. Kebler, Washington, D. C., secretary. The board of trustees elected were Drs. J. H. Beal, Urbana, Ill.; H. M. Whelpley, St. Louis; George H. Simmons, Chicago; S. Solis Cohen, Philadelphia, and Mr. F. J. Wulling, Minneapolis. By mutual consent the new committee on revision is constituted of seventeen physicians and thirty-three pharmacists and chemists. This committee organized by electing E. F. Cook, Philadelphia, chairman, and Charles H. LaWall, Philadelphia, secretary. Dr. H. C. Wood, Jr., Philadelphia, was appointed chairman of the Subcommittee on Scope. This is the committee in which physicians generally have the greatest interest as it has much to do with the selection of the drugs which are described in the Pharmacopeia. It was tentatively decided by the General Committee on Revision that the expression "mil" adopted in the last revision shall be abandoned in the new revision, returning to the old expression "cubic centimeter."

International Congress of Surgery.—The Fifth International Congress of Surgery will be formally opened at the Faculté de Médecine, Paris, July 19, at 2 p. m., to be followed

immediately by a discussion on blood transfusion, introduced by Dr. Jeanbrau, Brussels. Tuesday, there will be papers on cardiovascular surgery, by Drs. Tuffier of Paris, Sencert of Strassburg, Alessandrini of Rome and Charles Goodman of New York, and a discussion on surgical hematology, by Drs. A. Depage and Goovaerts of Brussels and Evarts A. Graham, St. Louis. Fractures of the femur will be the topic of discussion at Wednesday's session, to be opened by Drs. Patel of Lyons, Meurice Sinclair of the British Army Medical Corps, and Kellogg Speed, Chicago. The entire session on Thursday will be given over to papers on the treatment of tumors by radium and roentgen rays, by Drs. Régaud of Paris, Neville S. Finzi of London, Giuseppe Mioni of Rome and Robert B. Greenough, Boston. Papers on the prevention and treatment of tetanus by Drs. Donati of Modena, Cummins of London, Sieur of Paris, and Astley P. C. Ashhurst, Philadelphia, will conclude the scientific program on Friday. Clinics will be held in the Paris hospitals on Monday, Wednesday and Friday at 9 a. m., and business meetings are scheduled for Tuesday and Thursday at 10 a. m. In connection with the congress, there will be an international exposition of fracture apparatus, which will not be limited to members of the congress. Applications for space should be made not later than July 15 to Dr. M. Auvray, 50 rue de Pierre Charron, or at the Faculté de Médecine, rue de l'Ecole de Médecine, Paris, and should contain information as to the name, title and address of the exhibitor, the title of the exhibits, the amount of space required, expressed in square meters, and whether the objects are to be exhibited in glass cases or on tables, shelves or walls. Social entertainments will include a reception to the president of the congress, Dr. William W. Keen, Philadelphia, on Tuesday evening, and a banquet on Wednesday evening, both at the Palais du Quai d'Orsay. The American committee of the congress includes Drs. Charles L. Gibson, New York City, Richard H. Harte, Philadelphia, and Lewis L. McArthur, Chicago. Physicians who desire to attend the congress are advised to make steamer reservations at the earliest possible date, as there is every indication that the demand for accommodations will exceed the capacity of available steamers.

FOREIGN

Personal.—Dr. Ernest H. Starling, professor of physiology in the University of London, has gone to India to advise the British government with regard to the formation of a central medical research institute for India and will include in his travels Bombay, the Punjab, Bangalore, Calcutta, Delhi and Pasauli.

New German University.—It has been planned for some time to found a university at Cologne. The necessary formalities were completed with last year, and the new university has recently come into being very quietly. The various colleges and institutes have thus been collected into a state university which offers a chance to relieve the overcrowding of the university at Bonn. The new university starts with 2,000 students and over forty instructors, according to the *Paris médical*. It is rather a resurrection than a new creation, as Cologne was a seat of higher learning centuries ago, and the Akademie für praktische Medizin has been in existence as a municipal institution since 1904.

Physicians' Children in Austria.—Certain members of the profession in Austria have organized a central aid committee which is now collecting data in regard to the children in the families of physicians who would like to send them out of the country for a time. A question-blank has been sent to all physicians in the country, asking them to specify their wishes in the matter and list the eligible children. They must be over 7 and free from psychic and physical disease and enuresis. The committee hopes to get in touch with medical organizations in other countries and be able to place the children in homes elsewhere for a few weeks or months. The address of the committee is the Zentralhilfskomitee der Aerzte Oesterreichs, Vienna I, Börsegasse 1, Austria.

Tribute to Pure Food Champion in the Netherlands.—Dr. P. F. van Hamel Roos, an Amsterdam expert in chemistry, founded in 1884 a monthly devoted to investigation of adulterations in foods, drugs, etc., the *Maandblad tegen Vervalschingen*, and has published it regularly since. It has made him many enemies but also many friends, and a number of his friends arranged to make the April number of his monthly a souvenir issue in honor of his seventieth birthday. It contains a number of articles by leading chemists and physicians, and an interesting account of how the whole issue was planned and published without his knowledge,

while he was making up and correcting the proofs of the regular April number, which will appear later as the May issue. Of this jubileum-number one of the writers says, "This adulteration of the April number of the *Maandblad* is one of the few adulterations which have got past van Hamel Roos undiscovered."

The Profession in the German Empire.—The *Deutsche medizinische Wochenschrift* states that at the last census there were 31,602 physicians in the German empire. The number is now estimated at 40,000 although the extent of the empire has been much reduced, as many physicians have lost their positions in the colonies and other countries and have returned to the fatherland, while the medical officers dismissed from the military service swell the list of medical men and there is almost unprecedented flocking to the medical schools. The employment bureau of the Aertzeverband had 3,163 vacant positions to fill in 1914, but in 1919 there were only 1,614 vacancies. At present there are 4,000 applications on file, some of them waiting for more than a year, without any positions being open to candidates. Our exchange adds "The prospects for the future of the medical profession are consequently the worst that could be imagined."

Australasian Medical Congress.—The eleventh session of the Australasian Medical Congress will be held, after an interval of more than six and one-half years, in Brisbane, Queensland, August 23 to 28, 1920, under the presidency of the Hon. William F. Taylor. The work of the congress has been divided into eleven sections, as follows: medicine, presided over by Dr. Richard R. Stawell, Melbourne; surgery, presided over by Dr. H. S. Newland, Adelaide; obstetrics and gynecology, presided over by Dr. Fourness Barrington, Sydney; pathology and bacteriology, presided over by Dr. William J. Penfold, Melbourne; public health, presided over by Dr. John H. L. Cumpston, Melbourne; ophthalmology, presided over by Dr. A. Leo Kenny, Melbourne; otology, and laryngology, presided over by Dr. Herbert W. J. Marks, Sydney; diseases of children, presided over by Dr. W. F. Litchfield, Sydney; naval and military medicine and surgery, presided over by Col. George W. Barber, Perth; neurology and psychologic medicine, presided over by Dr. Henry C. Maudsley, Melbourne, and dermatology and radiology, presided over by Dr. T. G. Moldsworth, Sydney.

Deaths in Other Countries

Dr. Blanco Ledesma of Ciudad Bolívar, Venezuela, a writer on tropical pathology, committed suicide, Oct. 19, 1919.—Dr. Walter Georgi, assistant at the Serum Institute at Frankfurt on the Main, whose name has been prominent of late in connection with the Sachs-Georgi precipitation test for syphilis. He succumbed to severe influenza, aged 31.—Dr. F. Knauff, formerly professor of hygiene and legal medicine at the University of Heidelberg, aged 85.—Dr. Mariano Alcedán, a surgeon of Iquique, Chile, until recently when all persons of Peruvian birth were expelled from the city by the Chilean government.—Dr. H. Hessler, privatdozent for otology at the University of Halle, aged 69.—Dr. Moriz Benedikt, professor of electrotherapy and neuropathology at the University of Vienna, author of numerous works on these specialties, on "second life," brains of criminals, etc., aged 85.—Dr. C. T. Carvallo, called the founder of gynecology in Peru, the first incumbent of the chair for gynecology in the University of Lima, founder of the Academia Nacional de Medicina, and one of the founders of the Sociedad Peruana de Cirugía, now being organized.—Albert J. Chalmers, M.D., F.R.C.S., D.P.H., organizer and some time professor of physiology and pathology of the Ceylon Medical College, later director of the Wellcome Research Institute at Khar-toum, joint author with Dr. Aldo Castellani of a Manual of Tropical Medicine and accredited with much original work in pathology, notably on mycetoma, died, April 6, at Calcutta, aged 50, from infective jaundice.

LATIN AMERICA

Personal.—Drs. Jorge Vargas S. and Rafael Domínguez of Bogotá, Colombia, have been visiting clinics at Rochester, Minn., and Chicago.—Dr. Rodolfo Arce of Panamá is now in New York on his way from France, where he served during the war.—The organized ophthalmologists of Mexico have recently admitted ear and throat men to their society, so the name has been changed to the Sociedad Mexicana de Oftalmología y Oto-rino-laringología. Dr. Rafael Silva has been elected president and Dr. Vélez continues as secretary of the organization.

Government Services

Bill for Tuberculosis Hospital

Provision for the erection of a hospital for tuberculous patients in Colorado is made in a bill introduced by Congressman Timberlake of that state. The land must be donated without charge to the government and provision is made for construction thereon of a complete hospital plant at a cost of \$1,500,000. The hospital will be used for the treatment of tuberculous patients who are beneficiaries of the War Risk Insurance Bureau and the Public Health Service.

Health Conditions of the Army

Health conditions among troops in the United States are excellent. The admission and noneffective rates show a slight decline from the unusually low rates of last week. Epidemic diseases are still reported from the camps receiving large numbers of recruits. Camp Grant heads the list with 13 new cases of measles; Fort Oglethorpe, 10; Camp Humphreys, 8, and Camp Pike, 4. There have been reported throughout the various camps a few cases of pneumonia, malaria and one case of scarlet fever. The death rate is considerably lower than last week. There were 10 deaths, 6 of which were caused by communicable diseases, 5 dying of tuberculosis and 1 of pneumonia.

Government Regulates Use of Hot Springs

The government is making complete regulations with reference to the use of hot waters prescribed by physicians at the Hot Springs, Ark., reservation. This is accomplished by a provision in the Sundry Civil Bill which has just passed the House of Representatives and gives the Secretary of the Interior authority to assess and collect reasonable charges from physicians for the exercise of the privilege of prescribing the mineral water at the reservation. The money received from the exercise of this authority will be used in the protection and improvement of the reservation. The purpose of this regulation is to permit only registered physicians to prescribe the waters; to prevent improper charges, and to maintain high medical standards.

Public Health Service Takes Over Army Hospital

The Public Health Service will take over from the War Department the tuberculosis sanatorium at Fort Bayard, N. M.; it will be used for the treatment of discharged and disabled soldiers suffering from tuberculosis. The sanatorium is well fitted for the treatment of such patients by reason of its location and climate and the fact that outdoor life may be followed during a large portion of the year. The sanatorium will provide 1,000 beds. It is the intention of the Public Health Service to take only ambulatory cases of tuberculosis at Fort Bayard. Patients will be admitted only after careful observation to make sure that their condition is suitable for successful treatment at the high altitude of Fort Bayard. In general it is the policy of the Public Health Service not to move patients from their home localities, for experience has shown that such removal often has an unfavorable effect. Patients for this sanatorium will be drawn principally from the Middle West and South.

Appropriation Asked for Public Health Service

Forty million dollars is the amount which will be required by the Public Health Service in the year 1921 for medical, surgical and hospital service and supplies for war risk patients.

Dr. H. S. Cumming, Surgeon-General, has made formal request in a letter to the speaker of the House of Representatives that this amount be made available. In part Dr. Cumming says:

"The present rate of expenditures of the Public Health Service for hospital care and treatment of its beneficiaries is about \$2,387,000 per month or \$28,644,000 for the year.

"There are at present in government and civilian hospitals about 14,500 patients, and the service is furnishing about 69,500 office treatments and making 45,000 physical examinations per month. It is believed that the number will increase to 20,000 in-patients and that there will also be a corresponding increase in the number of office treatments and physical examinations during the coming year. It is therefore thought that the appropriation for next year should be at least 40 per cent. more than expenditures at the present time."

Psychology of Aviation

Dr. Harry M. Johnson, S. C., U. S. Army, in charge of the Department of Psychology of the Air Service Medical Research Laboratory, reports that during the year research was prosecuted along two distinct lines: an effort to gain a somewhat more intimate acquaintance with the effects of low oxygen on the integrity of response, and an effort to develop more sensitive tests for the detection of general aptitude for aviation work, and of its deterioration in the earlier stages of staleness. Extensive and detailed statistical study of the records of more than 6,000 classification tests for resistance to deprivation of oxygen was made. An attempt was made also to demonstrate the progress of impairment of behavior by the use of an objective record of the speed and accuracy which the subject can maintain in carrying on work of uniform difficulty as the supply of oxygen is being diminished. Researches were also made on the influence of diminished air pressure, simulating an altitude of 20,000 feet, on the time required for selective reaction to a number of combinations of signals visually perceived. A study of associative responses was also begun. It is believed that two forms of test, if sufficiently refined, might prove to be quite valuable in the diagnosis of aviaional ability and in exhibiting its impairment. These tests are (a) of the ability to control the coordinated activity of certain systems of voluntary muscles and (b) of the relative time required for selective reaction to one of three signals presented successively and in irregular sequence under a standard condition of observation and under a condition of observation so difficult as to be trying. The energies of the department were also devoted to the supervision of the psychologic features of the routine tests at laboratories, to the administration of classification tests at the local fields and to cooperation with other departments in the administration of tests in which the department of psychology was not directly interested.

Living Micro-Organisms in Paper

Dr. Galippe recently presented before the Academy of Sciences a very interesting communication on living micro-organisms in paper and their resistance to heat and the action of time. However little one may know about the processes of manufacture, it is not surprising that paper contains many micro-organisms. But it was generally supposed that these were destroyed in the course of the many operations which are undergone in the stages from pulp to paper. Now, according to the researches of Galippe, this is not the case, and all papers in use harbor living and cultivable micro-organisms. What is more, these organisms offer considerable resistance to heat, since filter paper may be subjected for half an hour to a temperature of 120 C. in an autoclave without the least effect on them. Chemists, therefore, will have to take certain precautions in definite cases. Galippe wondered if these infinitely minute objects which are so resistant to heat were any more sensitive to the action of time. With this in mind, he directed his attention to papers manufactured in the eighteenth and fifteenth centuries, and after repeated examinations, he was able to demonstrate the important fact that even in the fibers of these papers are found micro-organisms susceptible to cultivation and endowed with lively motion. In the paper of one incunabulum, Galippe found a bacillus at least morpholog-

ically identical with the tetanus bacillus. Encouraged by these results, he directed his researches to paper from Chinese manuscripts dating back to a very early epoch, certainly some centuries before the invention of printing. There again he found these microscopic beings in the fibers of the paper; planted in a favorable medium, the micro-organisms multiplied and appeared active and full of life. Going still further, Galippe decided to investigate whether living organisms could be found in Egyptian papyri, more than 2,000 years old. It is known that the Egyptians made their papyrus from the epidermis of the sheaths and stems of *Cyperus papyrus*. The strips were joined together, pressed and superposed, and made imputrescible, and thanks to the perfect methods of manufacture, they have been able to resist the destructive action of time, even to the present day.

Galippe was able to study a fragment of papyrus of the Ptolemaic epoch, that is, dating back to about 200 B. C. The structural elements of the papyrus were unchanged and the vegetable cells and fibers of which it was built up were found intact. The cells had not only preserved their form and reciprocal relations, but in some of them were again found perfectly distinguishable micro-organisms. Quite curiously, after three hours' contact with sterile water, these micro-organisms, immobile for centuries, regained their activity and showed themselves endowed with motion. More than that, when placed in a favorable culture medium they multiplied, and their mode of development and the different phases of their evolution could readily be studied.

Administrative Meddling in Medical Affairs

Dr. J. Noir, editor-in-chief of the *Concours médical*, has just published a long protest against the administration's meddling in medical matters. He cites, among other documents, a circular addressed to the principals of the Paris schools for distribution to parents of children having diphtheria. The circular is entitled: "Instructions to Families on the Precautions to Be Taken Against Diphtheria." The first part of the circular, which mentions the dangers and method of transmission of the disease and the necessity for isolation of actual and suspected cases, can readily be approved. Unfortunately, there follows a chapter on the treatment of diphtheria, in which the statement is made that this consists in the disinfection of the throat and nose, the "haunts" of the bacillus, by gargling, irrigating, inhaling or atomizing of medicaments which are capable of destroying the micro-organisms. It is also stated that when there is great danger of contagion or isolation of the children is impossible, it is necessary to give a preventive injection of antidiphtheritic serum not only to the carriers of the bacillus, but also to all who have been exposed to infection. Finally, it is averred that preventive serotherapy in children, if employed by the family physician according to certain rules, is absolutely without danger.

Dr. Noir demands on what authority the author of the circular forces on family physicians disinfection of the nose and throat which is so often an illusory procedure, and on what authority is based the obtrusion of preventive serum injections, when some of the physicians of children's hospitals, and these not the least competent, are opposed to its systematic use, claiming that, during the incubation period, a preventive injection may diminish or even destroy the effect of a therapeutic injection which the attending physician may later be obliged to make. But what seems particularly regrettable in the circular is the underscored statement that preventive serotherapy at the hands of the family physician presents absolutely no danger if certain rules are followed. What are these rules (which have not, however, been specified) which give assurance of safety from anaphylaxis and other accidents that occasionally can

assume a grave aspect? In the instructions accompanying the tubes placed on sale by the Pasteur Institute of Paris, one reads on the contrary that any injection of heterogenous serum may cause accidents, immediate or delayed, which sometimes require serious treatment. It is comprehensible that the foregoing circular, through the categorical statement which has been quoted, in case of even slight accident, risks discrediting the physician in the estimation of the family and greatly increases his responsibility.

Village Tuberculosis Settlements

An important deputation has waited on the minister of health to urge the establishment of village settlements in connection with the treatment of discharged tuberculous soldiers. It was pointed out that sanatorium treatment for tuberculosis, even when accompanied by training in a suitable occupation, had been found inadequate as a means of combating the disease. The general experience had been that patients who return from a sanatorium to their homes and former occupations are unable permanently to earn a living or maintain health. The patients should pass through a threefold course: first, of sanatorium treatment; second, of training, and third, of permanent settlement in suitable surroundings. The village settlement should be a natural development of the sanatorium and training colony, and the patient should be in a position to look forward to being able, on completion of his course of treatment and training, to take up his permanent residence in a settlement where, still in close touch with the sanatorium, he could work under conditions that would enable him to maintain his health and have his family or dependents with him. In the settlement the patient and his family would have to be housed, the necessary workshops and other buildings would have to be provided, and—in the case of the civilian—the patient's earnings would have to be supplemented; but the community would gain in the result by the prevention of the spread of infection and the fact that the tuberculous patient would remain a productive worker. As illustrating the results of establishing a village settlement on these lines, it was stated that at the Cambridgeshire Tuberculosis Colony, out of thirty patients who had passed from sanatorium treatment and training into the settlement, not one had died in four years.

Dr. Addison, minister of health, assured the deputation of his good will. There were, however, various difficulties to overcome. The success of a village settlement would depend even more on the personality of the man in charge than on the material provision made. As regards finance, the provision of ten settlements for not less than 200 patients each, as proposed by the Interdepartmental Committee, would, he considered, cost much more than the sum of \$5,000,000 suggested by it. Again, as minister of health he could not consider only the case of the ex-soldier; he had to consider also the civilian population, who had no pensions to supplement their earnings. Further, the Cambridgeshire Tuberculosis Colony was managed by a voluntary organization, but in the establishment of further settlements it would be necessary to rely in the main on local authorities. The problem was, therefore, one of much complexity; but a comprehensive scheme, dealing with all the various issues involved, was under discussion.

The Birth Rate

An address on "The Fertility of the Various Social Classes in England and Wales from the Middle of the Nineteenth Century to 1911" was given before the Royal Statistical Society by Dr. T. H. C. Stevenson, superintendent of statistics, General Register Office. He said it seemed likely

that large families promoted high mortality, and that high mortality promoted large families. It was evident that the decline in infant mortality during the present century was closely bound up with the decline in the birth rate. It was therefore all the more discreditable to the last quarter of the nineteenth century that during that period the rate of infant mortality did not decline, although the birth rate was steadily falling. In the deficient fertility of the classes which, having achieved most success in life, were presumably best endowed with the qualifications for its achievement, the nation was confronted with a new and formidable fact. The correspondence in time between the date of the Bradlaugh-Besant movement (1876) and the commencement of the fall in the birth rate in 1877 had always been obvious. The subsequent record of the decline was in fact precisely what might be expected on the supposition that it had been brought about through the neomalthusian views and methods having secured gradually increasing acceptance. After all allowances had been made, the professions, which formed the purest examples of middle-class occupations, were exceedingly infertile. The total fertility of all the professions tabulated, except nonconformist ministers, was underneath the lowest standard, though their very small rate of child mortality caused the clergy of the established church slightly to exceed that standard in regard to effective fertility. The exceptionally low figures for naval and military officers might be due to circumstances in their case rendering the maintenance of a family specially difficult; but the failure of this fine stock to reproduce itself was none the less to be regretted. The most remarkable instance of all was that of persons describing themselves as of "private means." In their case, presumably, the anxieties and difficulties which militated against fertility were at a minimum, but their fertility was also at a minimum. The reason might conceivably be that the more energetic and capable of the class referred to did follow some definite occupation, and that their fertility was higher than that of the inferior remainder of their class. The effect of female occupation in lowering fertility was clearly established. If we attributed to human volition the fall in the nation's fertility, these facts were readily explained; but if we refused to acknowledge this agency, it was necessary to assume the reduction of female fertility by nondomestic work as a law of nature.

Present Sociological and Economic Conditions of the General Practitioner

As a result of the war, the general condition of the profession has suffered a severe change, which is felt keenly in all quarters. One of the chief undesirable effects is the enormous increase in the number of graduated physicians. As long as the army in the field required large numbers of physicians for the medical care of the huge numbers of diseased, disabled or otherwise ill soldiers, the study of medicine was much favored and encouraged by the military authorities, and the examinations were so facilitated that the war-doctors, as they were termed, had really only nominal teaching. Naturally, these men try to augment their defective knowledge now in hospitals. Thus it happened that all vacant appointments as junior officers in the hospitals, in the dispensaries and ambulatories are now filled by these doctors. They all also desire to practice. Furthermore, in those parts of the old Austrian empire which now have been allotted to the new or successor states, large numbers of physicians of German nationality had been practicing for years. They all had to leave, because national and racial hatred became too strong against them. All public appoint-

ments were, of course, given to physicians of the respective nationality, without paying too much heed to the qualification. Naturally the men who had been maneuvered out of their living fled to Vienna, only to increase there the numbers of insufficiently occupied practitioners. While in 1913 the population was 2,250,000, with nearly 3,000 physicians, now we have more than 4,000 men to minister to the ailments of only 1,860,000 inhabitants (census of Dec. 31, 1919). According to statistics compiled by the Vienna Medical Council for assessment purposes, only 20 per cent. of the total number earn enough to keep up the standard of life they were accustomed to formerly. A little more than 60 per cent. may just manage to make both ends meet by hard endurance; the remaining 20 per cent. have to undergo incredible privations. Hunger, want of proper clothing and of reading matter tend to drive them to pauperism and proletarianism. This is no exaggeration. The conditions are appalling. Many of the middle-aged men have lost their private practice through their five years' absence from home with the army or as prisoners of war. Lately, the public has shrunk back from calling in a physician because the fees have been raised, although they are only doubled or trebled. Still, if a man charges 25 kronen for a call, he gets only what is worth about 12 cents in American money. Only a few practitioners can command fees of double that sum. Specialists are somewhat better off. The central medical organization tries to help whenever possible. By uniform action of all those concerned the organization succeeded, after a long struggle, in increasing the rate of payment of the panel or *kranken-kassen* physicians (sickness insurance clubs). These men get now double payment, in some instances even 60 per cent. more than that, and, besides, part of their rent is paid for them. Their fixed salary reaches from 14,000 to 18,000 kronen a year, specialists getting from 24,000 to 26,000, which represents material help to the individual. In the hospitals also an improvement of the prevailing economic position of physicians has been obtained. Uniform cooperation of the juniors and seniors resulted in the acknowledgment of the rule that every work must have its price. A salary of 900 kronen a month, as well as the right to buy their board for a small sum, has been conceded to the juniors, who hitherto have been unpaid. It must be added, however, that the organization had prepared everything for a medical strike and that in spite of the adverse feeling against such an inhumane weapon, it would have been put into action had this become necessary. The profession is well aware here that its most powerful weapon must not be used except for the most overwhelming necessity. As the government is scheming socialization of the profession, the medical strike will come into question when the problem of "to be or not to be" has to be decided.

An important step to improve conditions has been made by obtaining the system of free choice of physician for a large number of "panel" societies. Various unions of earning people tried to simplify matters for themselves by appointing a special physician for their members. The organization, however, endeavors to let all physicians participate in the possibility by encouraging such unions to adopt the system that permits the patient to call in the man whom he trusts without undue expense to himself, at the same time enabling the physician to be sure of his payment. Thus the civil service men, the postmen and the tramway men have agreed to this system, with fairly satisfactory results to both parties. On the other hand, a serious struggle is going on between the organization and the state as to the upper wage limit of the members of compulsory sickness insurance clubs (*kranken-kassen*). While the physicians want all men earning more than 24,000 kronen a year to be excluded from the panel, the other side wants to fix the limit at 48,000 kronen.

This would mean the end of private practice altogether, for the majority of laborers earn now between 24,000 and 48,000 kronen a year, while the classes hitherto called middle class have dropped out and drift hopelessly into pauperism. A complete shifting of the social strata has taken place, and the members of the profession are victims of this shifting, too. Many physicians had to apply for and accept gifts of charity, which are being tendered them in a most gracious and generous way from all parts of the world, neutral as well as previously enemy. Apart from other help, it must be mentioned how nobly the profession of Holland acted, by inviting several hundred children of Austrian physicians to Holland, where they remained three months and restored their semistarved, anemic bodies and their depressed souls. The average gain of weight was 6 kilograms (13 pounds) per child, and of growth, 5 cm. (2 inches). This shows how urgently the children needed the vitamins owing to the lack of milk, fat and eggs at home. Another noble deed was that of the Norwegian profession, whose members have sent several railway cars full of provisions for the Vienna physicians, containing fish, meat, chocolate, condensed milk, fat and flour. That this gift was gladly accepted proves under what stress large numbers of us are living here; it may be added that the "export" of physicians' children has been organized on a large scale for the summer time. Holland, Norway, Sweden and Switzerland vie with one another in magnanimous help for our profession.

Clinical Courses in the Summer Term

The official catalogue of the medical faculty of the Vienna University announces no less than 448 different classes and courses, given by twenty-one ordinary, 113 extraordinary professors and 152 assistants, and open to all students of the university on payment of the regular fees. It may be explained that ordinary professors are those who have been appointed as regular clinical teachers in a clinic, while the extraordinary professor has no clinic of his own, but is more of a guest at a clinic, but may have a ward under his special care. The fees have been raised now by an order of the board of instruction about six times more than they were before the war, and the postgraduate classes, ten times. This is very much for our students, but a trifle for the American or foreign physician. A private course costing 1,000 kronen costs, at the present rate of exchange, \$5; for this sum a quite first class course may be obtained. There will be delivered eight classes on physiology, thirty-five on pathologic anatomy, eighty-one on general pathology, forty-six on surgery, twenty-two on rhinolaryngology, twenty-nine on otology and forty-one on diseases of the skin, besides numerous others. On radiology only twelve classes will be held, but in the near future this branch of our art will be much better cared for, as it is intended to organize a huge central radiologic institute for all the public hospitals of Vienna, so as to insure the services of absolutely competent men for this important branch of medicine. There also the comparatively enormous quantities of radium and its active compounds, which are available in Vienna, will be turned to suitable use, enabling earnest studies to be conducted with them.

Statistics of the Winter Term

In 1919-1920 the winter term of the university lasted from October to March; 4,282 ordinary students and 221 extraordinary studied medicine in Vienna, among them 578 women. The previous term the figures were 3,823, with 557 women and 126 foreign students. The constant increase of medical students is well marked since 1910, and went up by bounds since 1915. The number of physicians has been increasing since 1915 far more rapidly than the increase of population, which has been practically nil for two years.

Deaths

Henry Holbrook Curtis ☉ New York City; Yale University, New Haven, Conn., 1880; aged 63; a specialist in laryngology and otology; visiting laryngologist to the New York Throat, Nose and Lung Hospital; consulting otologist to the Nassau County Hospital, Long Island, and consulting laryngologist to the Minturn Diphtheria and Scarlet Fever Hospital; a member and once president of the American Laryngological, Rhinological and Otological Society and New York Academy of Medicine, and a member of many foreign otological, laryngological and rhinological societies; died, May 15.

Don DeForest Grout, Waterbury, Vt.; University of Vermont, Burlington, 1872; aged 70; for eleven years superintendent of the Vermont State Hospital for the Insane, Burlington; consulting physician to the Fannie Allen Hospital, Burlington; local surgeon of the Central Vermont Railway; health officer of the town of Waterbury; president of the Vermont State Tuberculosis Commission, and vice president of the Vermont Society for the Prevention of Tuberculosis; a member of the legislature in 1888; died, April 19, from angina pectoris.

Salphronius H. French ☉ Amsterdam, N. Y.; Albany (N. Y.) Medical College, 1859; aged 82; formerly consulting surgeon to the Amsterdam Hospital; surgeon of United States Volunteers during the Civil War; for several years health officer of Amsterdam, and president of the Amsterdam City Library; one of the founders and since 1887 president of the Amsterdam Savings Bank; died, April 30, from angina pectoris.

Charles M. Lutterloh, Jonesboro, Ark.; Vanderbilt University, Nashville, Tenn., 1890; aged 57; a member of the Arkansas Medical Society, and president of the Tri-State Medical Association of Tennessee, Arkansas and Mississippi, in 1911; vice president of the American Trust Company, Jonesboro, and president of the Craighead County Board of Health; died, May 3, from heart disease.

Marshall Lebanon Brown, Brooklyn; Dartmouth Medical School, Hanover, N. H., 1867; aged 82; a member of the Massachusetts Medical Society; for three years surgeon of the Sixty-Ninth New Hampshire Volunteer Infantry, during the Civil War; for many years a practitioner of Boston; died at the home of his daughter in Flatbush, L. I., May 5, from heart disease.

William Brown Ewing ☉ Salt Lake City, Utah; Rush Medical College, 1885; aged 60; secretary of the Utah State Medical Association from 1912 to 1917; a specialist in neuro-pathy; captain, M. C., U. S. Army, and discharged, Jan. 8, 1919; examiner of the insane for the third district court; died in St. Mark's Hospital, Salt Lake City, April 24, from heart disease.

Frederick Sohon ☉ Washington, D. C.; Georgetown University, Washington, D. C., 1888; aged 53; captain, M. R. C., U. S. Army; professor of physical diagnosis in his alma mater; a medical officer of three expeditions under the command of the late Commander Peary, U. S. Navy, to the Arctic regions in 1897, 1903 and 1905; died, May 7.

Thomas James McCrory ☉ Racine, Wis.; Northwestern University Medical School, Chicago, 1905; aged 42; lieutenant, M. C., U. S. Army, and discharged Feb. 21, 1918; who was injured in an automobile accident, May 2, died in St. Mary's Hospital, Racine, from his injuries, May 5.

Alfred Jones, Cornersville, Tenn.; University of Nashville, Tenn., 1858; aged 81; a member of the Tennessee State Medical Association; a Confederate veteran; for two terms a member of the House of Representatives and for three terms a member of the state senate; died, April 16.

George Latham Underwood, Belmont, Mass.; Harvard University Medical School, 1858; a member of the Massachusetts Medical Society; superintendent and resident physician at the State Hospital, Rainsford Island, for several years; died recently.

John Ralph Pattee ☉ Dover, N. H.; Eclectic Medical Institute, Cincinnati, 1888; aged 59; county physician of Merrimack County, N. H., and chairman of the board of health; died in the Wentworth Hospital, Dover, April 27, from cerebral hemorrhage.

Emile Poirier, Salem, Mass.; Laval University, Quebec, 1881; aged 63; a member of the Massachusetts Medical

Society; one of the commission that had charge of the rebuilding of Salem after its devastation by fire in 1914; died, April 29.

Thomas Davidson Starbuck, Davenport, Iowa; State University of Iowa, Iowa City, 1902; aged 48; a member of the Iowa State Medical Society; died in Mercy Hospital, Davenport, May 11, from septicemia following the extraction of a tooth.

Benjamin Lucky Branch, Collierville, Tenn.; Memphis (Tenn.) Hospital Medical College, 1883; aged 63; a member of the Tennessee State Medical Association; president of the alumni association of his alma mater in 1909; died, April 25.

Robert N. Downs, Philadelphia; University of Pennsylvania, Philadelphia, 1856; aged 90; for many years a member of the consulting staff of the Germantown Hospital; a member of the College of Physicians of Philadelphia; died, May 1.

John William Bush ☉ Hot Springs, Ark.; University of Tennessee, Nashville, 1906; aged 51; lieutenant, M. R. C., U. S. Army, and discharged Jan. 3, 1919; a specialist in urology; was shot and killed by his brother-in-law, April 27.

George Miller Beard, Horseheads, N. Y.; College of Physicians and Surgeons in the City of New York, 1866; aged 80; a veteran of the Civil War; once a member of the New York General Assembly; died, May 1.

Alfred Kimball Hills, New York City; Hahnemann Medical College, Philadelphia, 1870; aged 79; for many years editor of the *Medical Times* and a member of the New York Academy of Medicine; died, May 2.

William J. Mairs, Newton, Mo.; Louisville (Ky.) Medical College, 1878; aged 65; a member of the Missouri State Medical Association; formerly a member of the state legislature; died, April 6, from carcinoma.

Adolph Zederbaum ☉ Los Angeles; University of Berlin, Germany, 1883; University of Dorpat, Russia, 1887; aged 71; died on the operating table in Methodist Hospital, Los Angeles, May 1.

William Barber Fellers, Roanoke, Va.; University of Maryland, Baltimore, 1910; aged 35; a member of the Medical Society of Virginia; died, April 23, from carcinoma of the kidney.

Zeba Darling French, Lawrenceville, Ill.; University of Iowa, Keokuk, 1865; aged 82; surgeon of the Third U. S. Volunteer Cavalry (colored), during the Civil War; died, April 27.

Mason Beach Hughes, Bloomsburg, Pa.; Jefferson Medical College, 1869; aged 78; formerly a member of the legislature from Luzerne County; died in a hospital in Philadelphia, May 6.

James Garland Boxley, Louisa, Va.; Medical College of Virginia, Richmond, 1863; aged 77; assistant surgeon in the Confederate Navy during the Civil War; died, April 23.

John Francis Canavan, Bridgeport, Conn.; Eclectic Medical College, Cincinnati, 1913; aged 32; died at the Wallum Lake (R. I.) Sanatorium, April 20, from tuberculosis.

B. S. Hunt, Sidney, Ohio; Pulte Medical College, Cincinnati, 1877; aged 69; president of the American Chemical Company; died, April 24, from cerebral hemorrhage.

William L. McGrew, Warren, Ohio; College of Physicians and Surgeons, Baltimore, 1890; aged 73; also a clergyman of the Methodist Episcopal Church; died, April 21.

Joab Stowell, Jr., North Amherst, Mass.; University of Minnesota, Minneapolis, 1890; aged 57; a member of the Massachusetts Medical Society; died, March 26.

Elizabeth S. Horr, Waterford, Me.; Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1872; aged 87; died, April 8.

John S. Holley, Bellevue, Macon, Ga.; Atlanta (Ga.) Medical College, 1882; aged 63; at one time city health officer of Tyler, Texas; died, April 20, from nephritis.

Edward Louis Miller, Mount Dora, Fla.; University of Maryland, Baltimore, 1884; aged 61; for many years a practitioner of Johnstown, Pa.; died, April 23.

John J. Patterson, Boaz, Ala.; Georgia Eclectic Medical College, Atlanta, 1878; aged 74; died in Etawah County, Ala., March 29, from cerebral hemorrhage.

Harry Gove, St. Andrew's, N. B.; College of Physicians and Surgeons in the City of New York, 1867; aged 74; died, January 28, from chronic gastritis.

William H. Snyder, Hastings, Mich. (license, Michigan, fourteen years of practice, 1900); aged 79; died, April 29.

Jonathan Price, Anna, Ill.; University of Tennessee, Nashville, 1882; aged 72; died, April 23, from septicemia following an infected wound of the foot.

Henry Kelby Gardiner ☉ Wakefield, R. I.; Dartmouth Medical School, Hanover, N. H., 1882; aged 63; died, April 30, from carcinoma of the liver.

William Allen Barnes, Martinsburg, W. Va.; Hahnemann Medical College, Philadelphia, 1895; aged 54; died, May 1, from pernicious anemia.

Esom G. Farris, St. Cloud, Fla.; Central College of Physicians and Surgeons, Indianapolis, 1883; aged 77; died, February 6, from influenza.

Wade Emmett Simpson, Indianapolis; University of Indianapolis; 1903; aged 42; died in Martinsville, Ind., May 3, from valvular heart disease.

William Henry Harrison Palmer, Napa, Calif.; Willamette University, Portland, Ore., 1889; aged 79; died, April 15, from senile debility.

Samuel Corbus Helmick, Commercial Point, Ohio; Miami Medical College, Cincinnati, 1871; aged 71; died, April 28, from heart disease.

Joel R. Davis, Marion, Ind.; Curtis Physio-Medical Institute, Marion, Ind., 1899; aged 80; died, April 18, from bronchopneumonia.

Luther Alvin Davis ☉ Wadena, Minn.; University of Minnesota, Minneapolis, 1901; aged 42; died, April 22, from Addison's disease.

Joseph H. Hooper, Dallas, Texas; University of Nashville, Tenn., 1866; aged 79; died in Thorp Springs, Texas, March 28, from senility.

Leidy Shimer Hagerty, Arlington, N. J.; University of the South, Sewanee, Tenn., 1900; aged 44; died, April 21, from heart disease.

Jesse D. Garr, Summitville, Ind.; Eclectic Medical Institute, Cincinnati, 1896; aged 63; died, April 15, from acute gastritis.

Ovila Clement Gelineau, Indian Orchard, Mass.; Baltimore Medical College, 1894; aged 48; died, March 29, from diabetes.

William H. Young, Springdale, Ark.; Kansas City (Mo.) Medical College, 1883; aged 73; a Confederate veteran; died, April 7.

Harwin O. Rockwell, Crown Point, Ind.; Chicago Medical College, 1881; aged 70; died, May 4, from valvular heart disease.

Edwin Llewellyn Chase ☉ Shrewsbury, Mass.; Baltimore University, 1898; aged 47; died in Smyrna, Me., April 29.

William L. Stone ☉ Pittsburgh; University of Pennsylvania, Philadelphia, 1880; aged 61; died, April 21.

John William Heacock, Talladega, Ala.; Tulane University, New Orleans, 1867; aged 83; died, April 27.

R. F. Harnesberger, Beckville, Texas; Medical College of Georgia, Augusta, 1884; aged 62; died, April 19.

John Magee, Troy, N. Y.; College of Physicians and Surgeons, Baltimore, 1880; aged 64; died, April 19.

John B. Cunningham, Norwich, Conn.; University of Vermont, Burlington, 1890; aged 52; died, April 1.

William A. Stephens, Cleveland; Western Reserve University, Cleveland, 1887; aged 59; died, April 15.

W. J. Trask, Great Cacapon, W. Va. (license, West Virginia, 1881); aged 62; died about April 23.

James Richards, Omaha; Missouri Medical College, St. Louis, 1890; aged 75; died, April 15.

Marriages

MARCUS BEEKMAN, Natchez, Miss., to Miss Lena M. Triche of Newellton, La., at Natchez, March 27.

NEIL SEWELL MOORE, St. Louis, to Miss Helen Hereford of Springfield, Ill., April 10.

GEORGE MICHAEL FITZGERALD to Miss Eileen Phelan, both of Chicago, recently.

NELSON MILES HOLDEN to Miss M. Alice Stengle, both of Brooklyn, May 3.

JACOB A. KOHN to Miss Jeanette Herma Schults, both of Chicago, May 6.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE MISBRANDED NOSTRUMS

How the Bureau of Chemistry Is Protecting the Public Against "Patent Medicines" Sold Under False and Fraudulent Claims

Seelye's Ner-Vena.—A quantity of this product, shipped in January, 1917, by the A. B. Seelye Medical Co. of Abilene, Kan., was analyzed by the Bureau of Chemistry, which reported that the preparation was a syrup containing alcohol and vegetable extracts among which were those of juniper, wild cherry, senna, gentian, sassafras, uva ursi (bearberry) and cinchona. "Seelye's Ner-Vena" was sold as a cure for pimples, loss of memory, "tired feeling," locomotor ataxia, bed wetting, female complaints, premature old age, malaria, pericarditis, impaired vision, hysteria, nasal catarrh and several other conditions. Naturally these claims were declared false and fraudulent. In March, 1919, the company pleaded guilty and was fined \$10 and costs. — [Notice of Judgment No. 6766; issued April 20, 1920.]

Hill's Rheumatic Pills.—These pills were shipped in June, 1917, by Harriet W. Belden, who traded as the H. W. Belden Co., Minneapolis, Minn. The federal chemists reported that analysis showed the pills to consist of vegetable extracts, including aloes, and 5 per cent. of mineral salts. They contained no salicylates, carbonates, iodids, bromids, alkaloids, ammonia or guaiac. "Hill's Rheumatic Pills" were falsely and fraudulently represented as a cure for rheumatism, neuralgia, gout, erysipelas, eczema, syphilis, pyorrhea, etc. In April, 1919, Harriet W. Belden pleaded guilty and was fined \$10.—[Notice of Judgment No. 6770; issued April 20, 1920.]

Jenkins' Rheumatism, Gout and Neuralgia Annihilator.—The Parker-Blake Co., Ltd., New Orleans, La., shipped in October, 1917, a quantity of "Jenkins' Rheumatism, Gout and Neuralgia Annihilator." The federal chemists reported that

analysis of the product showed that it contained over 46 per cent. alcohol, 1.5 per cent. salicylic acid, resinous plant extract and water. It was sold under the claim that it was a cure for acute and chronic articular rheumatism, muscular rheumatism, internal rheumatism, neuralgia, gout, paralysis and sciatica. These claims were declared false and fraudulent. In June, 1919, the company pleaded guilty and was fined \$10.—[Notice of Judgment No. 6771; issued April 20, 1920.]

Short Stop.—Henry M. O'Neil of New York City shipped a quantity of "Short Stop" in August, 1917. This, when analyzed by the Bureau of Chemistry, was reported to be a syrup containing licorice and wild cherry extracts, ammonium carbonate, small amounts of an antimony salt, benzoic acid, camphor, oil of anise and traces of an unidentified alkaloid. It was falsely and fraudulently represented as a cure for

pneumonia, consumption, bronchitis, colds, hoarseness and all throat and lung troubles. In January, 1919, O'Neil pleaded guilty and was fined \$15. — [Notice of Judgment No. 6777; issued April 20, 1920.]

Antiseptine.—The Cal-Sino Co., Baltimore, Md., shipped in March, 1918, a quantity of "Antiseptine." The Bureau of Chemistry reported that analysis of "Antiseptine" showed that the stuff was a powder composed essentially of about 48 per cent. anhydrous zinc sulphate, with about an equal amount of lead acetate, together with a small amount of copper acetate. "Antiseptine" was falsely and fraudulently represented as a cure and specific for fistulas, when in truth and in fact it was not. In October, 1919, the company pleaded guilty to this charge and also to the charge of misbranding a remedy sold for sick horses. It was fined \$100 and costs.—[Notice of Judgment No. 6810; issued April 23, 1920.]

Cassidy's 4X and P. G. S.—The Schuh

Drug Co., Cairo, Ill., shipped in December, 1916, and April, 1917, a quantity of "Cassidy's 4X" and "P. G. S." The federal chemists reported that "Cassidy's 4X" was found to consist essentially of aloes, colocynth, resins and a small amount of some mercury salt, alcohol and water; "P. G. S." was reported to consist of plant extract, including extract from a laxative drug, resin and not more than a trace, if any, of mercury, alcohol and water. Both "Cassidy's 4X" and "P. G. S." were falsely and fraudulently represented as cures for eczema, syphilitic affections, rheumatism, malarial poison and all affections of the skin caused by impure blood and as a relief for kidney and bladder dis-

PROPRIETARY VS. NON-PROPRIETARY

Compare the relative prices of identical substances sold under protected and non-protected names respectively.

Wholesale List Prices - April 1920.

Proprietary	Non-proprietary
Aspirin-Bayer 40.85 oz.	Acetylsalicylic Acid 40.16 oz.
Phenacetin 0.65 oz.	Acetphenetidin 0.27 oz.
Atophan 3.50 oz.	Cinchophen 2.00 oz.
Kelene (10 Grams) 0.56 tube	Ethyl Chloride (10 Grams) 0.45 tube
Duotal 1.90 oz.	Guaiacol Carbonate 0.80 oz.
Urotropin 0.60 oz.	Hexamethylenamine 0.21 oz.
Sulfonal 1.70 oz.	Sulphonmethane 0.80 oz.
Trional 1.90 oz.	Sulphon-Ethyl-Methane 1.00 oz.
Diuretin 1.75 oz.	Theobromine-Sodium Salicylate 0.70 oz.
Aristol 1.80 oz.	Thymol Iodide 1.00 oz.

ECONOMY, as well as SCIENTIFIC PRESCRIBING, should demand the use of NONPROPRIETARY NAMES whenever possible.

This is a greatly reduced reproduction of one of numerous posters shown at the New Orleans meeting in the A. M. A. Chemical Laboratory Exhibit. The original measured 22x28 inches. It is reproduced at the request of a large number of physicians who visited the exhibit.

eases. In October, 1918, the Schuh Drug Company pleaded guilty and was fined \$25 and costs.—[*Notice of Judgment No. 6841; issued April 23, 1920.*]

Hall's Canker and Diphtheria Remedy.—This product, which was said to have been shipped in August, 1918, by Selena D. Hall, Salt Lake City, Utah, was labeled as "an infallible remedy for diphtheria," a statement which, of course, was false and fraudulent. No claimant appearing for the property, the court entered a judgment of condemnation and forfeiture in December, 1918, and ordered that the product should be destroyed by the United States marshal.—[*Notice of Judgment No. 6836; issued April 23, 1920.*]

Red Cross Pile Cure.—William Davidson Rea, who did business at Minneapolis, Minn., under the name of Rea Bros. & Co., shipped in June, 1917, a quantity of "Red Cross Pile Cure" which was misbranded. These suppositories when analyzed by the Bureau of Chemistry, were found to consist essentially of cocoa butter, tannin, menthol, a lead compound, iodid, sulphate and possibly acetate. It was declared misbranded because the labels falsely and fraudulently represented it as a cure for blind, bleeding, itching and protruding piles, fistula, fissures, ulcers and all inflammation of the rectum and lower bowel. In April, 1919, Rea pleaded guilty and was fined \$5.—[*Notice of Judgment No. 6842; issued April 23, 1920.*]

"COTTON PROCESS ETHER"

In the Query and Minor Notes department of THE JOURNAL of February 21 some inquiries from physicians relative to "Cotton Process Ether" were answered. In referring to the composition of this product it was stated that the secretary of the Council on Pharmacy and Chemistry had asked the manufacturers, the Du Pont Chemical Works, for information on this point and one paragraph from the firm's reply was quoted. Another paragraph from the same letter was omitted and to this omission the manufacturers took exception, expressing the opinion that by it THE JOURNAL led its readers to infer that the concern had "refused to furnish any information whatever" regarding the composition of the ether. The following paragraph, italicized as in the original letter, is the one in question:

"Cotton Process Ether contains no components which do not occur in other anesthesia ethers. Its peculiar properties result from the thorough methods taken to exclude harmful impurities, such as aldehydes, peroxides, traces of acids, carbon monoxide, sulphur compounds, etc., and to include carefully regulated quantities of only such of the usual components as we have found to give distinctly beneficial properties to the ether. We are willing to state that in this class we consider properly prepared ethylene of greatest importance, but we have not announced which of the beneficial components of anesthesia ether we include in our ether, or the amount of such components."

As the quotation shows, the paragraph is informative in a negative rather than in a positive way in that it states what Cotton Process Ether is *not* rather than what it is. Since that time, however, the manufacturers have notified THE JOURNAL that they have definitely decided to present Cotton Process Ether to the Council on Pharmacy and Chemistry for consideration and that in preparing the data required by the Council will define Cotton Process Ether as follows:

"An improved anesthesia ether consisting of highly refined diethyl oxid ($(C_2H_5)_2O$), plus approximately two volumes of ethylene (C_2H_4), $\frac{1}{2}$ volume of carbon dioxide (CO_2), and 1 per cent. by weight of ethyl alcohol."

Spread of Vincent's Angina to Ear.—Dr. M. Oltoni de Rezende publishes in the *Boletim da Sociedade de Medicina de S. Paulo*, Brazil, a case of gangrenous perichondritis of the ear and otitis media from invasion by fusospirillar infection from the throat. Almost the entire ear and vicinity sloughed off down to the rear wall of the tympanic cavity. The other ear also showed beginning otitis media. Under local treatment with neutral solution of chlorinated soda and Peruvian balsam, and intravenous injection of neo-arsphenamin, the process was arrested and healed, but the child succumbed later to the cachexia and autointoxication.

Correspondence

OBSERVATIONS SUGGESTED BY "SYPHILITIC SCARS OF THE SPIRIT"

To the Editor:—Apropos of Dr. Collins' scholarly and altogether sympathetic case report chronicled in his recent communication (Syphilitic Scars of the Spirit, THE JOURNAL, May 1, 1920, p. 1216), one notes an admirable drawing of disease effect on that more elevated, moral entity (soul, spirit) which exists beyond purely mental cerebration. Yet I have wondered in respect to his conclusion of "miscarriage of therapeutic justice and mockery of studied effort" why the soul scar was stressed alone. Deterioration of mental capacity presented a fact the patient, himself, recognized as do many who are more frankly demented. Perhaps comment was so shaped because in the usual summing up of individual mental defect, intellectual capacity is alone emphasized, although moral disintegration, in some degree, is an invariable concomitant.

The case in question offers, too, a thought regarding treatment which I believe holds good today very often and is spoken of here only because, although not the attending but the consulting physician, Dr. Collins' detailed recital of treatment given makes the instance serve well as an example. Thus, it is related that months previous to the first symptom of meningeal irritation the blood serum had shown a +++ Wassermann reaction. Thereupon this patient received forty intramuscular injections of mercury. Two months previous to his attacks of vertigo, nausea and development of conspicuous mental symptoms, a facial paralysis had supervened. This had improved to some extent, but was still quite noticeable when Dr. Collins first saw the patient. Also, at this time the man looked very ill, was emaciated and pale, and during the examination was bathed in perspiration. The patient at this time weighed 98 pounds, his ordinary weight being 130 pounds. Laboratory tests were corroborative of the diagnosis of basilar meningo-encephalitis, the spinal fluid containing 150 cells per cubic millimeter. Treatment was changed to intravenous and intraspinal injections of arsphenamin, two of each, and daily inunctions of mercury. The serum and spinal fluid became negative, and the cells of the latter dropped to 11 per cubic millimeter. The patient's physical condition improved much, and his mental condition bettered up to a certain point, and thereafter remained stationary. He was given further intravenous injections of arsphenamin. Later in a sanatorium, antisyphilitic treatment with both arsphenamin and mercury was continued for another six weeks. Four months after coming under observation, his attending physician again put him under treatment continuing for about a year. Altogether the patient received about thirty intravenous injections, four intraspinal, and scores of injections and inunctions of mercury.

Repetition of this detail is set down because it brings out the patent fact of somewhat mechanical therapeutic procedure, although the use of the laboratory addressed to serologic conditions exhibits apparent scientific management. First, despite evidence of nonassimilation and reaction to mercury in the single manner initially given, no change of method is made in the face of disease progress shown by cranial nerve involvement and general physical deterioration. When arsphenamin injections are begun, an immediate betterment accrues to a degree and then stops. Nevertheless, thereafter it is arsphenamin, mercury and Wassermann test until arrival of that time which makes further attention appear useless.

Has this procedure, even after turning to arsphenamin for aid, lacked something in the interest of the patient? I think

so, and exactly that coefficient which is now so frequently lost sight of. Good clinicians and therapists of an earlier day, without the guidance of the identification of *Spirochaeta pallida*, the Wassermann reaction and the striking benefits of arsphenamin, and therefore more dependent on clinical watchfulness and tardier effects of mercury and iodine, would probably have adopted a less routine method. For the patient whose physical condition was below par, bed rest and full feeding was prescribed when it could be had, but particularly, when therapeutic effect from mercury became stationary "alteratives" were given. In the days of Rush, red clover, stillingia, burdock root, etc., were for a time substituted for actual specific treatment. Twenty-five years ago in clinics such as Neumann's or Kaposi's, Zittmann's decoction was given as interim medication between courses of mercury. Why? In modern vernacular, the handy phrase "to increase resistance" comes as a ready answer. To what? In an older day one would need to have said to the disease itself; today to the pale spirochete. This, however, was not the real thought. These clinicians noted that after "alterative treatment" (and an improved general condition), the system reacted anew to mercury and potassium iodide. Today we may theorize as to cause, saying, perhaps, that we thus reactivate essential organs of internal secretion. They knew nothing of these things, but held strongly to the lessons of experience and acted in accordance with them. The present day practitioner has great advantages over his elders who were without laboratory aids, but it would seem that just because of the diversions arising from the latter the modern sometimes becomes mechanical as to therapeutic concepts and hence, at times, falls short in respect to best treatment continuity. BERNARD OETTINGER, M.D., Long Beach, Calif.

"POISON IVY, OAK AND SUMAC"

To the Editor:—The editorial in THE JOURNAL, May 1, p. 1258, leads me to put together a few notes on my experience and observations. Poison ivy does not affect me unless there has been an unusual or prolonged exposure. When I first came to northern Indiana and found the swamp sumac or poison tree (*Rhus venenata* or *vernix*) I assumed that I was equally immune to this species of rhus and did not hesitate to break off a small branch for my herbarium—a proceeding I never repeated, for the next day I had a severe dermatitis of the hands, face "and elsewhere." Of course, I tried the remedies given in the books; but it was a week and more until the swelling subsided and another week until I was through shedding.

Once a year at least I go to the tamarack swamps (now almost extinct) to botanize; here the swamp sumac is common. In spite of all effort at prevention or avoidance I am usually poisoned more or less severely. For a long time I found no good remedy, no "cure"—only palliatives.

One year I had an unusually severe attack and then experimented freely. Among other things I applied a dilute solution of liquor formaldehydi to one hand, but this "set the skin afire" and required the soothing application of phenol solution; the cure was worse than the disease. Greatly to my surprise there was a marked improvement the next morning—almost a cure. It then occurred to me to combine phenol with the formaldehyd. The other hand was treated, and with equally good result.

Since then I have used this treatment as a matter of routine. I found that by freely applying a solution on coming out of the swamps there was no eruption, no poisoning at all.

I prepared a solution for dispensing. My usual formula is: liquor formaldehydi, 5 c.c.; saturated aqueous solution of

phenol, 10 c.c.; distilled water to make 100 c.c. (To this may be added a drop of methylene blue solution, as blue is a color that leads people to pause about using internally. To disguise the phenol odor, to which some object, a drop of some essential oil may be added).

In dispensing I supply a 4-dram vial with a swab in the cork and with the directions: Apply freely the first time; after that use sparingly every few hours, as needed.

Need it be added that a remedy that is "a power for good" may also be a power for evil? Some patients act on the principle that, if a little is good, more is better. The hardening or tanning effect of formaldehyd must be considered and explained to patients. The earlier the solution is applied, the better the effect.

ROBERT HESSLER, M.D., Logansport, Ind.

To the Editor:—Your editorial of May 1 on "Poison Ivy, Oak and Sumac" was of interest to me, as I was one of the unfortunate ones susceptible to poison ivy, etc. When about 10 years old I had a beautiful dose, covered from head to foot, eyes closed, etc.

A solution of zinc sulphate was used on my eyes that immediately dried off all of the poison ivy vesicles around the eyes. Since practicing medicine I have used it hundreds of times with good results. All irritation or even eruption can be prevented if it is used immediately after exposure. If used within twenty-four hours after exposure or ten hours after the appearance of the vesicles, it will abort the attack. If the case is not seen until the deeper layers of the epidermis are involved, the cure is slower but just as sure. To abort an attack, use 10 grains of zinc sulphate to 1 ounce of water. For later treatment, use half strength.

S. W. IRVING, M.D., New Britain, Conn.

To the Editor:—Relative to "Poison Ivy, Oak and Sumac" I have had splendid results from the use of equal parts of gum camphor, crystal phenol and the plain hydrocarbon oil, thoroughly rubbed in. Generally one application a day for two or three days is sufficient. It is to be understood that it is not to be applied over too extensive an area of skin surface at one time; also, in some cases a little more of the oil could be used, and in other cases less oil would give better results; but in most cases, equal parts of each will do the work.

ALBERT E. STOLER, M.D., Fort Wayne, Ind.

"BOTULISM DUE TO OLIVES"

To the Editor:—With reference to the questions concerning botulism raised in your editorial (THE JOURNAL, May 1, p. 1261), it may be desirable to answer the questions as fully as possible. The strain of *Bacillus botulinus* isolated from the Richmond, Calif., poisoning case was identified by Dr. Dickson as Type A, (too late for inclusion in the paper, p. 1220). The relish concerned in that poisoning case was made from ripe olives. The title of the paper was inclusive of the cases mentioned. The stuffed olives described were ripe olives stuffed. A certain portion of the ripe olives produced are marketed as stuffed olives. Pure culture experiments with *Bacillus botulinus* are accompanied by an objectionable odor. These odors are intensified when other organisms are present, as is usually the case. The doubtful character of odor as a safeguard must be recognized, but it must also be recognized that the physical examination of the can, including evidence of swell, turbidity, disintegration and odor, is the sole dependence of the ordinary consumer to protect himself against spoiled food. The reason for emphasis on the evidences of spoilage in our various publications has been confidence based on our observations that rigorous care in making the examinations required would

have prevented most, if not all, of the poisoning cases with which we have come in contact.

Mycologist, Bureau of Chemistry, U. S.
Department of Agriculture.

THERMOREGULATION OF REFRIGERATORS

To the Editor:—Having experienced a great deal of difficulty in the regulation of temperature of an ammonia and brine refrigerator, I wish to give my solution of the problem in the hope that other laboratories may benefit thereby. The thermoregulator installed in our refrigerator proved unsatisfactory and defective. On inquiry it appeared that the difficulty was that compressed air was used to open the valve admitting the chilled brine to the pipes. The compressed air entered the thermoregulator by a very fine port which was constantly becoming plugged by moisture and rusting. Learning this, we simply introduced a wash bottle of sulphuric acid into the air system before it reached the port. Since this wash bottle was installed, our refrigerator has not varied 3 degrees in temperature. We have used this device now for six months and find it entirely satisfactory.

LAWRENCE W. STRONG, M.D., New York.
Pathologist, Woman's Hospital.

POISONING BY MERCURIC CHLORID DOUCHES

To the Editor:—In THE JOURNAL, May 1, 1920, p. 1227, Dr. P. B. Bland of Philadelphia reported three very interesting cases of mercuric chlorid poisoning from vaginal injections. I am making a study of such cases and would appreciate the courtesy if you could furnish me with additional references from your journal or other journals or any medical works; also cases in which a saturated sponge or other mechanical device, together with mercuric chlorid, have been used. I have found a paragraph in Jewett's Obstetrics, but have not been very successful in finding other articles on the subject.

E. E. BRATTON, M.D., Philadelphia, Pa.

ANSWER.—Following is a list of articles on this subject:

DUCTLESS GLAND DISTURBANCES IN U. S. SOLDIERS DURING THE EUROPEAN WAR

To the Editor:—Being interested in material on diseases of the glands of internal secretion in U. S. soldiers in our army camps and at the front during the European war, I should feel much indebted to any physician who served as a medical officer in the army during the war who might be able to supply me with information in regard to this matter, particularly statistical relations, semiology, the incidence of these diseases in drafted men and in enlisted men who were subsequently on duty, and the measures taken in dealing with such cases. Any help I may receive in this matter will be highly appreciated and acknowledged.

Colorado January Examination

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the written examination held at Denver, Jan. 6, 1920. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 13 candidates who took the physician's and surgeon's examination, 5, including 1 osteopath, passed and 7, including 6 osteopaths, failed. Twenty candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Reliance Medical College	(1910)		83
Kansas City College of Medicine and Surgery	(1917)		75
Jefferson Medical College	(1915)		92
Kyoto Imperial University	(1910)		75
FAILED			
University of West Tennessee	(1918)		40
LICENSED BY RECIPROCITY

Minnesota January Examination

Dr. Thomas S. McDavitt, secretary of the Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held at Minneapolis, Jan. 6-8, 1920. The examination covered 15 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 6 candidates examined, 5 passed and 1 failed. Fifteen candidates were licensed by reciprocity. Fifteen candidates, including one osteopath, were licensed on Army and Navy credentials, and one candidate was licensed on Red Cross Service. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Rush Medical College		(1919)	90
Harvard University		(1911)	93
University of Minnesota Medical School ..	(1917)	88, (1918)	86

Book Notices

BODILY CHANGES IN PAIN, HUNGER, FEAR AND RAGE. An Account of Recent Researches into the Function of Emotional Excitement. By Walter B. Cannon, M.D., C.B., George Higginson Professor of Physiology in Harvard University. Cloth. Price, \$3 net. Pp. 311, with illustrations. New York: D. Appleton and Company, 1920.

This little volume, appearing first in 1915, and now reprinted with only slight changes, is a well written, popular account of the investigations that Dr. Cannon and his pupils have made in this field of physiology during the last twenty years. The book is of equal interest to the physiologist, the psychologist and the medical practitioner. Since it was written, our conception of the rôle of epinephrin in normal bodily functions has undergone considerable modifications, owing chiefly to the work of Dr. G. N. Stewart of Cleveland. The final chapter, on "Alternative Satisfaction for the Fighting Emotions," is an attempt to apply physiologic investigations at Harvard to the problems of social control.

AN INTRODUCTION TO GENERAL PHYSIOLOGY, WITH PRACTICAL EXERCISES. By W. M. Bayliss, M.A., D.Sc., F.R.S., Professor of General Physiology in University College, London. Cloth. Price, \$2.50 net. Pp. 237. New York: Longmans Green & Co., 1919.

This little volume follows the general plan of the large book on general physiology written by this eminent physiologist a few years ago. It is essentially a new type of elementary textbook of physiology for beginners in this science, in that it deals exclusively with the chemical and physical processes in the organism, with little or no reference to anatomic structure or histologic detail. While the book is purposely elementary, medical men who graduated twenty-five or thirty years ago could peruse the first part of the volume with profit, as it presents the main advances in the application of the laws of chemistry and physics to vital phenomena that have been made during this period.

Medicolegal

Illegal Obtaining and Dispensing of Morphin Sulphate

(*Trader v. United States (U. S.), 260 Fed. R. 923*)

The United States Circuit Court of Appeals, Third Circuit, in affirming a judgment of conviction of defendant Trader, a physician, of violating the Harrison Narcotic Law, says that, as the defendant was not registered as a dealer in the drug and had not paid the special tax, as required by Section 1 of the act, and as he had dispensed the drug to persons without the written orders required by Section 2, and also, by means of the statutory order forms, had obtained large quantities of the drug, he was unquestionably guilty of the violations charged, unless it appeared, in the one case, that the drug was dispensed or distributed in good faith, in the course of his legitimate professional practice, and in the other case that it was acquired for use therein. The principal error assigned was the refusal of the trial judge to charge the jury, without qualification, that the act "does not limit the amount of morphin sulphate which a physician may prescribe or administer to his patients." He charged that while the law "does not in specific terms" create such a limitation, "it does provide that such drug must be prescribed in the course of his professional practice only." It is true that the act does not in specific terms state how much morphin sulphate may be prescribed or administered by a physician to his patients. It does, however, exempt physicians, in the dispensing and distributing of the drugs covered by the act, from the requirements of Section 2 only in such cases as are "in the course of his professional practice only." The regulations promulgated by the commissioner of internal revenue, pursuant to the authority conferred by Section 1 of the act, provide for separate and distinct registration by dealers and physicians. Hence, if the defendant dispensed the drug in question not in the legitimate practice of his profession, he became a dealer in the drug and was required

to register as such. Therefore, whether he was a dealer depended on whether or not he was dispensing the drug in the course of his legitimate practice as a physician. Likewise, the legality of his acts in obtaining the drug by means of the statutory order forms was dependent on whether he acquired it for use "in the legitimate practice of his profession." Manifestly, therefore, so far as the issues in this case were concerned, there was in the act just such a limitation as the trial judge stated. Accordingly, the qualification which he made in the requested instruction was not only proper, but, as it seems to this court, was quite necessary in order that the jury might not be misled and confused. It was next urged that the trial judge was not justified in stating, as he did in his charge, that, while the Harrison act is a revenue measure, "its clear purpose . . . is to restrict the distribution and use of opium and its derivatives to medicinal purposes only." It is assuredly within the discretion of a trial judge, in charging a jury, to state the purpose, as he conceives it, that Congress had in passing any given act. If an erroneous statement of such a purpose may be considered reversible error in any case, the court is entirely clear that, although the Harrison act was passed pursuant to the taxing power of Congress and is clothed in the garb of a revenue act, the judge did not misconceive or misstate the broad underlying purpose which Congress had in passing it, and therefore that no harm was done the defendant by the statement in question.

Illegal Sales of Narcotic Drugs by Physicians

(*Oakshette v. United States (U. S.), 260 Fed. R. 830*)

The United States Circuit Court of Appeals, Fifth Circuit, in affirming a judgment of conviction of defendant Oakshette of violating the Harrison Narcotic Law, says that the indictments charged sales to have been made by him, not in pursuance of written orders, given by the purchasers, on forms prescribed by the commissioner of internal revenue. The proof showed that he was a physician and had registered with the collector of internal revenue. He was authorized to administer the prohibited drugs, without obtaining a written order, if they were administered "in the course of his professional practice," but not otherwise. The government contended that the drugs administered by him were not administered in good faith, in the course of his professional practice, but to gratify the desire or appetite of the patients or purchasers. He contended that they constituted legitimately medical treatment for his patients. The issue so made was submitted to the jury.

The contention of the defendant was that it was not within the issues presented by the indictments, since they merely charged sales illegal because not in pursuance of written orders. The only prohibitions of the statute are (1) sales by unregistered persons and (2) sales by registered persons not in pursuance of written orders. The defendant could be charged only with having made the one kind or the other. As he had registered, he was not guilty of the first. If, having registered, he made sales or dispensed the drug without obtaining a written order, he was guilty of the second kind, unless because he came within one of the excepted classes. If he administered the drug only in the course of his professional practice, he came within one of the excepted classes, and was not guilty. If, however, he administered the drug not in the course of his professional practice, then he did not bring himself within any of the excepted classes, and so came within the operation of the prohibition of Section 2, against selling or dispensing not in pursuance of a written order, and was properly charged with that offense. As a registered person he could have been charged with no other offense, since the act creates no other out of the act of selling or dispensing by registered persons. It does not make it a separate offense for a physician to administer the drug when it is not done in the course of his professional practice. His doing so merely removes him from the classes exempted from the operation of Section 2, and leaves him subject to the punishment prescribed by Section 2.

Dispensing the drug, though by a physician, if not in the course of his professional practice, is in legal effect a sale;

and, being one, can be legally made only in pursuance of an order form; and the offense of doing it without one is necessarily that of selling or dispensing not in pursuance of a written order, in violation of Section 2 of the act.

The defendant complained that the evidence was insufficient to convict him. That there was evidence in the record from which the jury might well have inferred that the defendant administered the drug, not in good faith to cure his patients or alleviate their present suffering, but to satisfy their craving, as addicts, for the drug, was clear from the constant quantities over periods of as much as three months, during which the record showed it was furnished to a number of persons by the defendant. The sufficiency of his explanations as to why he failed to reduce the amounts, especially as to those he testified he was attempting to cure of the drug habit by the method of reduction, was for the jury to determine.

Liability of Physicians—Advising Local Physician

(*Thornburg v. Long (N. C.), 101 S. E. R. 99*)

The Supreme Court of North Carolina, in affirming a judgment of nonsuit in this action against a physician to recover alleged damages, says that the law governing the liability of a physician to his patient is well settled. While there is an implied contract that the physician or surgeon who undertakes to treat a patient will use all known and reasonable means to accomplish the object for which he is called to treat the patient, and that he will attend to the patient carefully and diligently, there is no guaranty that he will cure him, or that he will not commit an error of judgment. The law implies only that he not only possesses, but that he will employ in the treatment of the case, such reasonable skill, care and diligence as are ordinarily exercised in this profession. But a physician or surgeon possessing the requisite qualifications and applying his skill and judgment with ordinary care and diligence to the diagnosis and treatment of a patient is not liable for an honest mistake or error of judgment in making or prescribing the mode of treatment, when there is ground for reasonable doubt as to the practice to be pursued.

The testimony of the plaintiff in this case tended to prove that he began suffering from a swollen arm, and, after being treated for about a week by his local physician and receiving no relief, he was sent by his family physician to the hospital of the defendant for treatment. The plaintiff told the defendant of his great suffering, and asked him to operate on him or give him some relief from his pain. The defendant examined the plaintiff at once, removed his shirt to the waist, found his arm swollen from elbow to neck, examined his back, looked over him, asked him as to his habits, private history relating to women, took blood from him for analysis, put him to bed, called on him next morning to make further examination, gave him some medicine, and told him he could not do anything until he had a report from the analysis of his blood—would not say it was tuberculosis. The defendant took some blood from the plaintiff's arm and sent it away to be tested, and the next day the plaintiff returned to his home to await the further orders of the defendant. In a few days the defendant wrote to the plaintiff's local physician that the plaintiff's blood showed the strongest positive Wassermann test, and that he had a bad case of syphilis, and nothing but heroic treatment would save his life. The plaintiff testified that he was a virtuous man and had never had sexual intercourse with any woman other than his wife, who was a woman above reproach. After he returned from the defendant's hospital, his local physician lanced his arm, and a few days thereafter it was again lanced, by another physician, and he had entirely recovered.

The question was, Did the defendant, under the facts as testified to by the plaintiff, use that skill and diligence which he was required to use, and was there evidence tending to prove the plaintiff's contention of negligence sufficient to be submitted to the jury? There was evidence, sufficient to go to the jury, that the defendant made an erroneous diagnosis when he concluded that the plaintiff suffered from the effects of syphilis, but there was not a scintilla of evidence that he

was incompetent or negligent. On the contrary, the evidence offered on behalf of the defendant indicated that he stood very high in his profession, and that in diagnosing the plaintiff's case he followed recognized and established practice. The fact that the defendant wrote to the plaintiff's local physician that the examination showed evidence of syphilitic poison was no basis for an action. It was the defendant's duty to communicate to him the conclusion he had reached. The communication was wholly privileged. The court thinks the defendant's motion for a nonsuit was properly allowed.

Competency of Evidence as to Insanity

(*Davis v. Alderson (Va.)*, 100 S. E. R. 541)

The Supreme Court of Appeals of Virginia says, in this case wherein plaintiff Alderson sued defendant Davis for the specific performance of a contract by the latter for the purchase of a tract of land, and the defendant's defense was that when the contract was entered into he was temporarily insane, that three physicians were called as witnesses and examined as experts. None of them had seen the defendant at or near the time of the transaction, and they were not called on to testify from personal knowledge; but a question was propounded to them which ended with the inquiry, Would you regard a man in the financial condition of Mr. Davis, making the two trades and purchases above, as a man whose mind was in a proper condition and a man sane at the time or not? Their testimony was not expert testimony at all, but the mere inexperienced opinions of these gentlemen, and should have been excluded.

Testimony of lay witnesses as to the sanity or insanity of a person is admissible in evidence when it appears that the witness has had sufficient opportunity, by observation, to form an opinion worth considering; but the opinion of the witness should be preceded by a statement of his opportunity for observation, and of the facts observed. The value of such testimony is dependent very largely on the character of the witness, his opportunities for observation, the facts observed, the interest; bias or prejudice of the witness, his capacity and intelligence in making and relating his observations, and other circumstances which affect the weight to be given to oral testimony generally. Usually such testimony, when general and continuous insanity is not involved, is not esteemed of much value, except so far as the opinion of the witness is justified by the data observed.

Whether the defendant's purchases were wise or foolish, if he had contractual capacity, was immaterial. If courts were permitted to pass on the wisdom or folly of contracts, or if that were a test of sanity or insanity, the business of the country would soon be involved in inextricable confusion. Allusion was made more than once to the fact that the defendant was of the great age of 62 years as affecting, in conjunction with other things, the validity of the contract; but the court will take judicial notice of the fact that men of greater age than that so far retain the confidence of the government in their mental capacity as to be placed in judicial positions where they have to pass on the validity of contracts made under identical circumstances with the case in judgment. Every one is presumed to be sane until the contrary is made to appear by him who alleges it.

The defendant was bound by his contract.

"Insane Delusion" Difficult of Accurate Definition

(*Trustees of Epworth Memorial Methodist Church et al. v. Overman et al. (Ky.)*, 215 S. W. R. 942)

The Court of Appeals of Kentucky, in reversing a judgment that invalidated a will which was contested by the children of the testator on the sole ground that it was executed under an insane delusion as to their feelings and attitude toward him, says that an "insane delusion" that renders one incapable of making a will is difficult of accurate definition. It is much more than bias or prejudice, or any merely incorrect mental attitude. It is rather a wholly irrational state of mind on a particular subject; that is, such a mental state as is supported by no evidence whatever, and therefore purely a product of the imagination. As has been said, insane delusion

should be distinguished from prejudice or error, as well as from eccentricity. It differs essentially from some rational belief, not well founded, however perversely the testator may have clung to it. An ill-founded belief, not actually insane, does not destroy testamentary capacity. And where one indulges in an aversion, however harsh, which is the conclusion of a reasoning mind, on evidence no matter how slight or inaccurate, his will cannot be on that account overturned.

MEDICAL ASSOCIATION OF GEORGIA

Seventy-First Annual Session, held at Macon, May 5-7, 1920

The President, DR. E. G. JONES, Atlanta, in the Chair.

Forty-Three Gallbladder Operations

DR. R. M. HARBIN, Rome: In this series of cases there were seven men and thirty-six women. The youngest patient was 26, the oldest 77. The duration of stay in hospital was about the same for cholecystostomy as for cholecystectomy. In five cases, gallstones were unexpectedly discovered. Seventy-eight per cent. of the patients gave histories of devitalized teeth; 53 per cent. had had abscessed teeth; 31 per cent. had had tonsillitis; 50 per cent. had had rheumatism in some form; 15 per cent. had had jaundice, and 50 per cent. had had some form of septicemia.

Breast Tumors, Special Reference to So-called Cystic Mastitis

DR. C. W. ROBERTS, Atlanta: Chronic cystic mastitis bears a definite relationship to cancer of the breast, and must be considered a precancerous lesion. This disease becomes cancerous in one out of five cases observed to their final outcome. So-called cystic mastitis in patients above the age of 35, with suspicious malignant tendencies, should be treated by a radical operation of the Halstead type. In that special class of cases in younger women, unassociated with frank malignant tendencies, and when for individual reasons the patient's future would be more or less blighted by the complete operation, the conservative plan should be adopted. This disease furnishes about one third of breast lesions, discovered on routine examination.

Treatment of Cancer with Radium

DR. C. C. HARROLD, Macon: Radium is only a handmaid to surgery, and there are many cases in which it would be criminal to use radium instead of operating. Radium should not be used in cancer of the breast, except for treating recurrent nodules. It should not be used on the lip instead of doing the radical neck dissection. However, in cancer of

the lip it will do just as well as the old operation of dissecting out the growth from the lip without getting the neck glands, and with nothing like the accompanying deformity and parrot mouth occasionally seen. Radium should be used for the local growth; a few weeks later, after all local growth has been cleaned up, the radical operation on the neck should be performed. The value of radium is unquestioned in the inoperable cases of cancer of the uterus. In the treatment of early cancer of the cervix, there is no primary mortality. The patients are immediately relieved from all their symptoms, and Janeway asserts that unless the disease has already gone out into the parametrium we have a permanent cure.

Medical Aspects of Surgical Cases

DR. WILLIAM HOWARD LEWIS, Rome: There are three distinct phases in which the medical mind should be of material advantage to the surgeon: (1) in assisting to establish a diagnosis; (2) in differentiating between and evaluating the relative weights of coexistent medical and surgical conditions in a given case, and (3) in cooperating during the convalescence and ultimate restoration to health.

Mobilization Versus Immobilization

DR. THEODORE TOEPEL, Atlanta: Splints, usually of plaster of Paris, are necessary in the treatment of most fractures. As soon as possible splints are discarded. Then a mixed treatment is adopted, massage and mobilization being practiced daily after only a brief delay, the splints being applied between times. When a limb is immobilized, not only are no steps taken to restore the circulation, but a condition of total disuse is enforced, which must itself lead to further loss of vitality. Even a healthy bone tends to undergo atrophy, and that so rapidly that the bones of a child's limb which have been placed in plaster are liable to undergo spontaneous fracture after the second month. That external splints fail to restore circulation is also shown clinically by the fact that a leg still shows signs of edema when a plaster splint is removed a month or six weeks after fracture.

Gunshot Wounds of the Chest and Their Treatment

DR. T. C. DAVISON, Atlanta: In my series of more than forty cases I was impressed with the frequency of pneumothorax as a complication, and I often found one or more openings in the diaphragm, with hernia of the abdominal viscera. In those cases of chest injuries that were given the so-called expectant treatment, too often at the necropsy it was found that serious complications were present which could be ascertained only by open operation. The indications for operation are: fracture of the ribs; bleeding from the parietal wound; a sucking wound into the pleural cavity; retention of large foreign bodies within the chest; a large hemothorax which cannot be evacuated by aspiration; serious internal hemorrhage, and any wound below the sixth rib on account of possible injury to the diaphragm and abdominal viscera. The operation should be performed as soon as possible after the receipt of the wound, unless the patient is in shock. Contraindications for operation are small, clean, punctured, through-and-through wounds of the upper thorax with the absence of serious symptoms; shock, and pneumothorax of the opposite side.

The Obstetrician's Obligation

DR. GARNETT W. QUILLIAN, Atlanta: The accoucheur owes four obligations to the new-born babe: (1) proper care of the eyes; (2) proper care of the navel; (3) applying only to the male child, circumcision, except in rare cases; (4) an effort to see to it that the child is not robbed of its proper food, its mother's milk.

Utility of Influenza-Pneumonia Vaccine in Pregnancy and Postoperative Conditions

DR. MARION T. BENSON, Atlanta: During the present epidemic I had under observation and treatment forty-five pregnant women, and none of these women died when they received a preventive dose of vaccine. Ten of these women had had influenza in their homes, and found it necessary to

render personal care to those who were sick; but all escaped the disease. Five others, who were constantly exposed and had to do nursing, developed mild cases without troublesome complications. Three women miscarried, but did not develop pneumonia or any other complication, and made uneventful recoveries. Three women who did not receive any influenza-pneumonia vaccine before they were infected developed pneumonia and died in an alarmingly short time.

I used Type IV influenza-pneumonia vaccine brought out by General Hospital No. 6.

Early Diagnosis as a Means of Reducing the Death Rate from Cancer

DR. J. L. CAMPBELL, Atlanta: I have selected a group of cases to show the importance of removing breast tumors during the early or precancerous stage. Fifteen were benign and thirteen were malignant tumors. Of the former patients, all are now well and strong, while only five of the latter are living; one has a recurrence and is being treated with the roentgen ray; three who have passed the five-year period are well, while I have not heard from a sixth in some months. In two of the women the tumors had been present between four and five years; in others, only a few weeks to a month or two. In all cases the principal symptom was a lump; in a few, pain was noticed during the menstrual period. In both the intracystic adenoma and the intracanalicular fibroma there had been a bloodstained discharge from the nipple before the enlargement was noticed. In eight of ten cases the diagnosis was easy, as the clinical picture was complete.

Relief of Menorrhagia and Metrorrhagia by Roentgen-Ray Treatment

DR. W. A. COLE, Savannah: Roentgen-ray therapy is now considered by many to be the method of choice in all cases of menorrhagia of the menopause in which the presence of carcinoma is definitely excluded either by the history or by a diagnostic curettement, and in those cases not presenting a large, soft myoma which is likely to undergo malignant degeneration later. It is also used in cases of menorrhagia, or metrorrhagia in young women, when there is a small mucous fibroid, when no gross pathologic condition is demonstrable, and in cases presenting a large myoma in which there is a definite surgical risk.

Spinal Anesthesia

DR. W. L. COOKE, Columbus: Spinal anesthesia may be used with absolute assurance of perfect anesthesia in any operation of any magnitude below the umbilicus. In my hands it has been an absolutely safe procedure. I have used this method of anesthesia in all kinds of operations from a case of simple hemorrhoids to a complete hysterectomy, and from a simple amputation of the leg up to a bone graft for ununited fracture of the femur. I do not know exactly how long the anesthetic effect lasts, but I have performed operations that required anywhere from fifteen minutes up to almost two hours, without the patient's experiencing any pain whatever.

Hypertrophic Stenosis of the Pylorus

DR. W. WHATLEY BATTEY, JR., Augusta: During the last few months I have operated in three cases of hypertrophic stenosis of the pylorus in infants, aged 3, 5 and 6 weeks, respectively.

I did the Rammstedt operation.

Some Diagnostic Problems of the Chest

DR. E. C. THRASH, Atlanta: Every physical examination of the chest, when the patient is really sick, should be checked up with the roentgen ray. Our latest two epidemics of influenza have frequently caused two disturbances that have been exceedingly difficult to differentiate from tuberculosis. These are the hemic infections and the endocardiac disturbances without valvular lesions. Both disturbances present practically the same symptoms as tuberculosis, and the fact that the physical signs of tuberculosis are not present does not enable one to rule out the latter disease. A

blood culture will often clear up this problem; but if it is negative, one is still confronted with a problem. A careful study of the roentgenogram and a survey of the past history of the patient will often throw light on these cases.

Local Anesthesia in Abdominal Surgery

DR. L. W. GROVE, Atlanta: I have had no hesitancy in recommending the method in well defined acute conditions or in simple drainage. I would hesitate to advise local anesthesia in obscure inflammatory masses, in which event some form of anoci-association anesthesia, preferably local anesthesia with gas-oxygen, is unquestionably the safest and surest, and is the anesthetic of choice.

Importance of Ureteral Stricture in Abdominal Diagnosis

DR. GEORGE Y. MASSENBURG, Macon: A patient sent to me for operation with a diagnosis of appendicitis had had recurrent attacks of pain in the appendical region for ten months, the attacks lasting from a few hours to several days, with a constant soreness near McBurney's point. She had some nausea with the attacks, but no vomiting. In the more severe attacks, she occasionally had some pain in the right lumbar region, and some bladder irritability. She never passed any blood in the urine. A catheterized specimen of the urine was negative. Roentgen-ray examination revealed a small shadow in the region of the lower end of the ureter. On cystoscopic examination, the bladder appeared normal. An opaque catheter in the right ureter showed the shadow to be a small stone in the ureter. With a wax bulb on the catheter, a stricture was found in the ureter at about the region of the stone. The stricture was dilated with a 4 mm. bulb. The patient had considerable pain for about twenty-four hours, but left the hospital in a few days. One month later the patient was still free from symptoms, but had not passed the calculus. She was dilated a second time, April 10, 1919. She is still free from all symptoms, but has not passed the stone.

SOUTH CAROLINA MEDICAL ASSOCIATION

*Seventy-Second Annual Meeting, held in Greenville, S. C.,
April 20-21, 1920*

The President, Dr. E. W. PRESLEY, Clover, in the Chair

Inducing Rapid Growth of Epithelium Over Areas Denuded of Skin by Use of Zinc Oxid Adhesive Plaster Applied Directly to Raw Area

DR. LINDSAY PETERS, Columbia: If the denuded area shows acute inflammation with abundant suppuration, it is dressed daily with dichloramin-T suspended in oil, making a 1 per cent. mixture. When the wound is clean, adhesive plaster is placed immediately on the wound, without the interposition of gauze or other material, the wound being completely covered either with a single piece or with overlapping straps. Dressings should be done daily. No antiseptics are used. The action of the adhesive plaster may be explained by its possible ionic effect, by the production of edema, carrying out the idea of Bier's hyperemia, by the exclusion of air, destroying aerobic bacteria, and by excess of serum bringing a new army of antibodies into play.

New Treatment of Enuresis in Children

DR. WILLIAM R. BARRON, Columbia: In so-called idiopathic enuresis, the treatment consists in emptying the bladder with a catheter under aseptic precautions, and then instilling through the catheter into the bladder 1 ounce of a 3-per cent. argyrol solution, letting some remain in the bladder for from one-half to one hour, when it is voided. This is done every day or every other day, as indicated. The strength of the argyrol is gradually increased until 10 per cent. is borne without irritation. It is not well to use strengths of argyrol that irritate, because they will not be retained and will make the child object to treatments. In boys, instead of inserting a catheter, the argyrol is injected through the urethra with a bulb syringe, washing out the urethra with plain sterile water after the argyrol is forced into the bladder.

Folliculosis Versus Trachoma in Our Schools

DR. J. W. JERVEY, Greenville: In the early stages many cases of trachoma present clinical appearances indistinguishable from follicular conjunctivitis by any diagnostic method, macroscopic or microscopic. In a few weeks or at most a few months, the essential changes characteristic of trachoma will appear if this is the disease; if they do not appear, then we are dealing with something else. No case of trachoma can be cured in the sense that all traces of it can be eliminated. What the mistaken ophthalmologist cures is folliculosis, and the profession and the public should realize this fact. And here the cure is infinitely worse than the disease. Trachoma is no respecter of age, while folliculosis occurs among schoolchildren and is an adenoid hypertrophy. When it exists, one will invariably find in the same child hypertrophied tonsils and nasopharyngeal adenoids, and refractive errors seem practically always to be present in these cases. This condition has been mistaken for trachoma by officials of the United States Public Health Service, and children have been operated on needlessly. It is important to have a well trained ophthalmologist on the state board of health.

Malignant Tumors of Male Breast: Report of Case

DR. GEORGE BENET, Columbia: Benign tumors of the male breast do not seem to differ essentially from those found in the female. My case was one of fibro-adenoma with a malignant degenerative process in a man, aged 18. He complained of a small lump in the left breast of four months' duration, which caused him no inconvenience until after a slight blow on the breast two weeks before coming under observation. The boy was somewhat feminine in appearance, and his muscular development was not that of a boy of 18. There was no glandular involvement.

The Proctoscope in General Diagnosis

DR. F. M. DURHAM, Columbia: All patients suffering from symptoms referable to the rectum that do not yield to ordinary treatment should be given a proctoscopic examination. No surgeon should operate on a patient for hemorrhoids, especially of the bleeding variety, without first giving his patient such an examination. All patients suffering from back, uterine and bladder symptoms, and all cases of intestinal indigestion and auto-intoxication, which are refractive to treatment and have no definite pathologic lesion, should also undergo proctoscopic examination.

The Incision of Tumors for Diagnosis

DR. KENNETH M. LYNCH, Charleston: The ordinary manipulation of a tumor in the course of examination may be the source of much more stimulation than would be an incision. If we weigh the evidence for and against and the advantages and disadvantages of submitting a specimen for microscopic examination, both to the patient and to the surgeon, I believe microscopic examinations would become of more general practice. The story of no tumor is complete without a microscopic examination, whether preoperative, at operation or postoperative, as the circumstances surrounding each case demand.

Metabolism as an Aid in Diagnosis, Prognosis and Treatment of Hyperthyroidism

DR. STUART MCGUIRE, Richmond, Va.: There has not yet been sufficient experimentation or practical experience with basal metabolism to determine its exact clinical value. Like the thermometer, it promises to be a most valuable agent; but, like the thermometer, its record must be considered together with the patient's clinical symptoms. A patient with hyperthyroidism may have a high metabolic rate and not be as seriously sick as another with a lower rate who has structural changes in the heart, liver or kidneys. The metabolic rate of the patient is a definite index of the degree of hyperthyroidism present, and therefore very valuable in making a diagnosis. The onset of hyperthyroidism is so slow that it is difficult to recognize it in its incipience; and here the metabolic rate will clearly differentiate it from hysteria, neurasthenia, tuberculosis, and other conditions with which it may be confused. Again, in the later stages,

there develop symptoms due to degeneration of the heart, liver or kidneys, and it is difficult to say how much the patient suffers from hyperthyroidism and how much from damage to the vital organs. Here also a determination of the basal metabolism will be of value, not only for diagnosis but for prognosis as well. Usually, a patient's clinical symptoms coincide with his metabolic rate; but sometimes they do not. Patients with high metabolism and moderate tachycardia are more seriously ill than those with moderate metabolic increase and a very rapid heart action. In treating a patient for hyperthyroidism, the estimation of the metabolic rate is of value first to determine the safety of the measure to be employed, and second to ascertain its efficiency.

Autointoxication

DR. EDWARD H. GOODMAN, Philadelphia: I protest against the use of this term and the making of a diagnosis without evidence which at the present moment has not been universally accepted as unquestionable. Not every one who uses the term autointoxication understands by it what he wishes others to understand, and which in the hands of many means so many varied things. The term is a loose one loosely used.

Renal Calculus

DR. G. T. TYLER, Greenville: This report includes five cases of kidney stone; four patients have been operated on and one patient is still under observation. All were cases of single stone in women: four were in the left kidney and one in the right. Except in one case, all the diagnoses were made and confirmed by differential urinary and roentgen-ray findings. In this case the diagnosis was appendicitis, but was disproved by obtaining a specimen of urine from the right kidney. At the time of the attack, the patient had boils over the buttocks and back; the kidney infection was probably secondary to them. Though I used the wax-tipped catheter, in only one instance was there a scratch noted on it. This was because the stone lay outside of the course of the catheter. Except in one case the stones were all removed by pyelotomy. In one case in which both kidneys were involved, the induction of adequate drainage, together with the injection of silver nitrate and mercurochrome-220 into the kidney pelvis resulted in increasing the phenolsulphonephthalein elimination from both kidneys to 25 per cent. in twenty minutes. In these cases and in three others not cited in detail, I feel that good results have been obtained only by the conservation of the kidney function and by the effort to make the patient a safe risk before undertaking operation.

Medical Certificates of Insanity

DR. J. W. BABCOCK, Columbia: I wish to appeal to physicians for greater care in the making out of certificates of insanity. There is an indifference on the part of physicians which is by no means confined to South Carolina, but is common all over the country. The physician who signs a certificate of commitment without making a careful examination and going carefully into the case does a serious injustice to the patient and to himself. It is well to remember that relatives may sometimes allege that a person of whom they wish to get rid is insane when such is not the case.

Hospital Standardization in South Carolina

DR. J. R. YOUNG, Anderson: Last October, only 198 of our 671 hospitals of 100 or more beds could measure up fully to the minimum standard set by the American Medical Association. One year before that, only eighty-nine could qualify. We provide one hospital bed for every 1,100 of our population, while the average ratio is one bed for 486. The medical profession is responsible for any defects in the quality of hospital service. The rank and file of the profession can help in attaining state-wide improvement of hospitals by measuring the efficiency of the hospital to which they refer their patients by the yardstick of the minimum standard. If physicians will (1) become familiar with the aims of hospital standardization; (2) study closely the progress which the hospital of their choice is making, and (3) lend their full support and cooperation to it, they will aid tremendously this organized effort of hospital improvement.

Significance of Nervousness in Children

DR. J. F. MUNNERLYN, Columbia: It is becoming more and more evident that in children who have certain slight or grave defects in their nervous make-up, something in their development has not gone right. This does not mean that they are intellectually deficient, but that something has gone wrong in the realm of mental functions from which spring desires and motives. There should be some organized plan for the study and control of these early apparently trivial abnormalities. The work of psychiatric clinics in Massachusetts and New York has been most gratifying, and where this phase of health work has been instituted it is considered just as important as that which has to deal with the control of tuberculosis, venereal diseases, etc. Many unfortunate individuals, who are at present steering directly to an inevitable mental breakdown, can be helped to live happy and efficient lives.

Diagnosis of Atypical Malaria

DR. FRANCIS B. JOHNSON, Charleston: Pulmonary tuberculosis is probably more often mistaken for malaria, and malaria for tuberculosis in the Southern states, than any other disease, because of the widespread prevalence of both. Not infrequently both exist. The atypical malarial conditions are more usually associated with the chronic infections of the pernicious type, particularly those not characterized by a definite paroxysm. Among conditions that may be ascribed to malaria are found diarrhea, dysentery, various types of neurasthenia, paralysis, ulcerative stomatitis, multiple gangrene, orchitis, and many diseases of the eye—these cases have been proved by the finding of the plasmodium of malaria, and the patients have recovered under quinin treatment.

Use of Mercurochrome in Treatment of Some Urologic Conditions

DR. T. M. DAVIS, Greenville: Sixty gonococcal urethritis cases in males have been treated by this drug in 2.5 per cent. strength. The treatments were controlled by frequent examinations of the smears. In almost all cases the discharge had ceased within twenty-four hours, and in all cases by the end of the third day. The average length of time to effect a cure was twenty-six days. In none of the female patients (ninety-five) treated has there been an extension of the disease to the endometrium.

The Capillary Heart

DR. W. F. R. PHILLIPS, Charleston: In the circulation of the blood, as generally described, the all sufficient kinetic force is the heart. Some recognition, however, is given to auxiliary kinetic factors represented in the contractions of the skeletal and splanchnic muscles and to the suction-pump action of the respiratory mechanism. A great fall in pressure takes place in transition from arteriole to capillary; a lower to a somewhat higher pressure prevails in the veins. It is obvious that other factors than the left ventricle must enter into and complete the systemic circulation. To these factors is applied the name capillary heart. Many experiments in the injection of fluids into arterioles and capillaries have convinced me that there is a maximum point of resistance in the transition from arteriole to capillary, though it cannot definitely be stated whether it is solely resident in the capillary or partly resident there and partly in the surrounding muscular tissue. Certain experiences indicate that the capillaries of different parts and organs are differently endowed with powers of resistance. That living capillaries have the power to contract, even to the extent of completely obliterating their lumen, is a well known fact; but the significance of this property in its relation to the phenomena of circulation does not seem to have attracted the attention that its possibilities seem to attach to it.

Significance and Treatment of Fever During Infancy and Childhood

DR. J. LABRUCE WARD, Columbia: It is only in rare instances that it is advisable to use antipyretics other than hydrotherapy. The physician must be guided by the general condition of the patient, rather than by the disease or the degree of fever.

Bone Changes in Feet Following Fracture of Vertebrae.—Two cases are reported by Bryan. He says little attention has been given to the fact that fracture of the vertebrae is followed by sensory disturbance in the legs and feet accompanied by bony changes.

Diaphragmatic Hernia.—Among approximately 15,000 cases examined with the roentgen ray at General Hospital No. 1, three cases of diaphragmatic hernia were found. The diagnosis in each case was first made by roentgenographic examination.

Milk and Tuberculosis.—It appears that the control of human tuberculosis depends to an appreciable extent on a much closer control of bovine tuberculosis. To control this menace, Swift suggests, first, to allow the farmer something nearer the true value for a condemned animal. He would then be a little more willing to help in the fight. Second to start a demand for tuberculosis-free milk. This can be done and ought to be done by education of the physician first, who in his turn will educate his patients. Some farmers have said that they would make tuberculosis-free milk if there was a market for the product and if they could receive a price that would allow them a better margin in which to stand the losses.

Milk-Borne Epidemic of Typhoid.—The interesting circumstances in the epidemic studied by Bigelow and Berg were: the small number of persons who developed typhoid among those who may have ingested the organism; that dairymen who are carriers, though excreting typhoid organisms for weeks and months, rarely contaminate the milk; the value of the positive Widal as an aid in the detection of carriers.

Blood and Blood Serum in Therapy.—Special attention is drawn by Johnson to the use of blood in infants with anemia and malnutrition. Infants with jaundice, delayed clotting time and a tendency to hemorrhage may be benefited greatly by the injection of blood. It may also be useful in the treatment of purpura. Hemolytic tests should be made in every case.

- *Meningococcal Activity of Blood. T. Matsunami, Tokyo.—p. 51.

Neisser-Wechsberg Inhibiting Phenomenon.—The work reported on by Thjøtta may be summarized as follows: The inhibiting phenomenon of Neisser and Wechsberg is of a specific nature. It is to be found in active as well as in inactive serum. It develops during the immunization and can be found in a very high degree in dysentery immune serum. In active serum from immunized animals examined without the addition of foreign complement, the phenomenon presents itself as a complete abolition of a normal bactericidal action. The inhibition is due to antibodies that arise during the immunization or during the natural disease. These antibodies are not identical with the agglutinins, the bacteriolysins or the precipitins. They must be considered as specific antibodies, which combine with dissolved antigen to form molecular complexes, that have a marked tendency to absorb complement and to withdraw it from the bactericidal antibodies. The titer of inhibition is directly proportional to the employed dose of complement. With a small dose of the latter, smaller doses of inhibiting antibodies can be demonstrated than with a larger dose of complement. The inhibiting antibodies do not affect the bacteria themselves, nor can they be removed from the serum absorption with an emulsion of the homologous bacilli. They can be demonstrated in serums that lack any bactericidal action.

Meningococcal Activity of Blood.—It was found by Matsunami that normal rabbit blood and serum may kill virulent normal meningococci in vitro within three hours. The meningococcal activity in vitro of normal rabbit blood was found to be increased up to a certain limit by the intravenous injection of the living and autolyzed meningococci. After that, further immunization did not appear to increase bactericidal activity, was generally rather irregular and not infrequently even decreased meningococcal activity of the blood. The more highly immunized rabbit's blood was found sometimes less bactericidal than that of slightly immunized rabbit's blood. The meningococcal activity of normal rabbit's serum has been found not to be increased by artificial immunization and also to be comparable with that of defibrinated blood of an immune rabbit. The meningococcal activity in vitro of immune rabbit's blood was found by the pipet method to be distinctly stronger than that of the serum, of defibrinated blood or of blood consisting of blood cells and serum or of citrated blood. It was suspected that at least one factor in explaining the higher meningococcal activity in vitro of immune rabbit's blood compared with defibrinated blood, citrated blood and serum, lies in the influence of coagulation of the blood, which is permitted in the regular test as described, favoring the phagocytosis of meningococci. Matsunami maintains that a meningococcal blood test cannot be accepted on the basis of his investigations for the purpose of measuring or determining the artificially induced immunity against meningococci.

Urinary Tract Purpura.—Stevens and Peters report a group of cases that presented as a distinguishing feature a purpuric condition confined, in at least the majority of cases, entirely to the urinary tract. This condition was marked by an acute onset, temperature of an irregular type, general febrile symptoms, frequency of urination, dysuria, gross hematuria, cylindruria and a reduction of the phenolsulphonephthalein excretion. The disease, as far as it could be observed, tended to run a prolonged subacute or chronic course. Occasionally, acute relapses occurred. Pathologic examination of the lesions obtained from the bladder wall by means of a cystoscopic punch revealed submucous hemorrhages unaccom-

panied by any signs of inflammation. Suggestive vascular changes were observed in some specimens. Bacteriologic examination of blood and urine proved negative. Attempts to determine the etiology of this condition or to identify it with any known disease were unsuccessful. The authors believe the condition is sufficiently distinctive to merit consideration as a new disease.

Urologic Diagnosis Complicated by Riedel's Lobe of Liver.—O'Connor has found that Riedel's lobe offers a positive complication to the urologist in making a diagnosis even in carefully studied cases. The occurrence of this condition is sufficiently frequent to be borne in mind when determining the nature of a palpable mass in the right flank or abdomen. In the presence of acute infection in the urinary tract, the occurrence of a linguiform lobulation makes a differentiation very difficult and the apparent indications are for an immediate surgical procedure. The mass in each of O'Connor's two cases could be outlined definitely on palpation and moved slightly on respiration. The notch in the elongation gave the physical signs usually found on palpating the upper pole of a low lying or enlarged kidney. In the cases described, circumstances prevented getting ureteropyelograms on the right side. These would have served to assist in ruling out the supposition that the palpable mass was kidney. In both patients the gallbladder and surrounding structures were normal, contrary to Riedel's original conception of the etiology of the prolongation. In both individuals the structures of the elongation felt and appeared to be normal liver tissue.

Nurse as an Anesthetist.—Ehrlich maintains that a nurse is not fully competent to administer anesthetics. She may be trained in the mechanical processes of the administration, and may even have had a few months' instruction in physical diagnosis. But this at best can give her only a superficial experience, and does not prepare her to meet the conditions with the matured judgment which comes only with a thorough knowledge of medicine. She is no more qualified to do the work of an anesthetist than a nurse with operating room training and a superficial knowledge of anatomy and the mechanical skill which has enabled her to master the steps necessary to open an abdomen and remove an appendix, for example, would be qualified to do the work of a surgeon. The matured judgment which comes only with a general knowledge of medicine is wanting in each case. The fact that nurses administer anesthetics in a few large clinics is by no means proof that it is a good thing either for the patient or for the institution. Ehrlich believes that a hospital which entrusts work of this nature and importance to a nurse assumes a grave responsibility. Justice to the patient demands that he be served with the utmost skill, not only in the mechanical administration of the anesthetic, but in the ability to cope with any emergency which may arise during the anesthesia. If a nurse finds that she is interested in this work, she should study medicine, and so become thoroughly qualified from every point of view.

Sarcoma of Round Ligament.—In Moench's case the diagnosis was made before operation. The tumor was situated in front of the external inguinal ring. According to Frankl's nomenclature it was, therefore, a preinguinolabial growth. The tumor in toto was about the size of a grapefruit. Microscopic examination showed that the main part of the tumor consisted of a myofibroma whose connective tissue had undergone hyaline degeneration in many places. The clinical course of the case showed the extreme malignancy of the new growth. The woman died eight weeks after the opera-

tion, despite the fact that at the time of operation there had been no evidence of sarcoma present, either in the ligamentum rotundum or in the inguinal glands.

Speedwell System for Care of Infants.—In 1902 Chapin developed what is known as the Speedwell system that represents a sustained effort so to regulate and systematize boarding out as to place its good effects at a maximum and its possible bad effects at a minimum. This has been accomplished by developing what may be called a unit system of intensive boarding out. A unit is a neighborhood that has been selected after a survey has been made to learn the general conditions of healthfulness and the number of good homes that may be available in the locality. There is then inaugurated a constant oversight, especially as to diet and hygiene, on the part of a salaried physician and nurse who are thoroughly familiar with this class of cases and competent to deal with them. The children are kept indefinitely, until digestion and assimilation have improved sufficiently to result in a permanent increase in weight and strength. Accordingly, work is continued during the whole year. In each neighborhood foster mothers are trained and they become fairly expert in this work. In comparing the results of institutional care with systematized boarding out, it will be found that both mortality and morbidity are less under the latter plan. Chapin describes a plan in operation which consists of collecting units in the city that are in constant communication with units in the surrounding villages. Thus far the Speedwell has developed three of these units.

Yeasts in Human Colon.—Feces obtained from the rectum of a patient complaining of severe headache and sciatica, and who had had tuberculosis ten years previously, when inoculated into glucose agar, yielded a profuse growth of yeast cells, associated with a diplococcus and extremely few colon bacilli. The patient had never received the yeast treatment. Later, the same organism was isolated, and also what appeared morphologically to be a different type of the same yeast. A saline suspension of a pure agar culture was injected into rats. Those injected intraperitoneally showed, scattered all over the peritoneum, many small and large rounded nodules, translucent, with centrally located whitish spots, very suggestive of a tuberculous lesion. The three rats injected subcutaneously had developed a localized, tumor-like granuloma having a general similarity to the peritoneal lesions, but no metastases were found. Intravenous injection of mice resulted in death from embolism within twenty-four hours. This study is not yet sufficiently advanced to justify any conclusions as to the relation of these yeasts to the pathologic condition. Further laboratory studies are being made.

Manic Depressive Insanity and Raynaud's Disease.—Ward suggests that manic-depressive insanity is a form of Raynaud's disease affecting the frontal region of the brain.

Intestinal Pathology in Functional Psychoses.—Cotton and his associates have been able to restore 270 patients out of a total of 410. By reexamining the remaining ones they were able to find local foci which had been overlooked and by January, 1920, this number had been reduced to 100. In

other words, 75 per cent. of this group, or 310, when the local foci of infection found in the teeth, tonsils, stomach, and cervix were eliminated, were able to be discharged and returned to their respective homes. The remaining 25 per cent. apparently did not react to the treatment and remained unimproved. The object of the investigation, of which this is a preliminary report, was to search further for possible sources of infection, mainly in the lower intestinal tract. This group suggested terminal ileac and colonic trouble because of frequent "bilious attacks" during youth; habitual constipation, sometimes alternating with diarrhea; intermittent attacks of abdominal pain, and, not infrequently, a history given by the mother of intestinal disturbances beginning in early infancy. From an experience with these cases, the authors were convinced that all patients who showed any tendency toward chronicity, or who did not improve under the routine treatment directed toward the removal of infection in the teeth, tonsils, stomach and cervix, were cases in which a thorough investigation of the lower intestinal tract was indicated with a view to surgical intervention. A detailed report is made showing how many patients recovered, how many were improved and how many were benefited.

Arrhythmias and Psychopathic States in Cardiovascular Disease.—One hundred histories of cardiovascular patients were analyzed by Satterthwaite to discover the interrelation as to frequency between the arrhythmias and the psychopathic states in cardiovascular diseases. The results were as follows: With arrhythmias, taking them as predominating features in these cardiovascular cases, of the first fifty the following abnormalities were noted in seven: morbid apprehension, one; depression, four; defective mentality, two; total, seven, or 14 per cent. Of the second fifty, depression was noted in three. Total in the 100 cases: Psychopathies in ten. The range was from 6 to 14 per cent. Without arrhythmia: Of the first fifty cases the following abnormalities were noted in ten: morbid apprehension, four; depression, two; neurasthenia, three; hyperexcitability, one. Of the second fifty cases the following abnormalities were noted in ten as follows: depression, six; melancholia, two; hysteria, one; defective mentality, one. Total of arrhythmias without psychopathies, 20 per cent., as against 10 per cent. of arrhythmias with psychopathies. In the same series with respect to tachycardias, 6 per cent. were associated with psychopathies, while in 11 per cent. of the cases there were no psychopathies. Evidently, then, there is no reason to believe that either arrhythmias or tachycardias are etiologic factors of any great moment in the psychopathies. On the other hand, the reports of the Manhattan Hospital for the Insane

show that in the psychopathic cases cardiovascular disease was present in about one third of the psychopathic patients.

In Satterthwaite's 100 cases the neuropathies were represented in 33 per cent. Some of them resulted from direct action of the heart or blood vessels, some from reflex causes of varying character. Satterthwaite concludes, however, that arrhythmias are not active factors in causing psychopathies; tachycardias even less so. The incidence of cardiovascular disease in causing psychopathies in general, and in being contributing causes of death in them is from 32 to 35 per cent. On the other hand, senile psychoses may be associated in a similar manner with cardiovascular disease in 77 per cent.; psychoses with cerebral arteriosclerosis in 80 per cent. of the cases. With respect to the incidence of such neuropathies as migraine, anginoid attacks, neuralgias, pareses, or paralyzes and tremors, Satterthwaite's figures put it at 33 per cent. Most of such neuropathies, however, are either incidental or accidental associates of the cardiac or vascular diseases.

Dental Infection as Cause of Mental and Nervous Diseases.

—Mills states that a score or two of cases have passed through his hands or have come to his knowledge in which important nervous and mental diseases have been attributed to dental infection. In these, with the united support of physicians, roentgenologists and dental surgeons, the teeth in small or large numbers have been removed with results not only unsatisfactory but often so harmful as to impress Mills with the futility, if not the criminality of the procedure. Some of the diseases which came under his observation in connection with the question of dental infection are dementia praecox, manic depressive insanity, epilepsy, neurasthenia, hysteria and psychasthenia. The teeth in these cases were freely sacrificed, without a single result of convincing value.

Focal Infection and Mental Diseases.—Cotton believes that it can be shown by clinical evidence that certain types of mental diseases are caused by toxemia resulting from focal infection and that clearing up these foci of infection results in the recovery of the patient. He claims to have confirmation of this belief from the pathologic and bacteriologic studies made after death, and says he has yet to find a single case with a functional psychosis without accompanying infection. He discusses particularly dental infections, and the influence of unerupted third molars, and cites briefly a number of illustrative cases.

Incidence of Malignant Disease of Gallbladder.—During the first six months of 1918, Erdmann observed nine carcinomatous gallbladders out of sixty-eight operations on the gallbladder. During the second half of 1918, three cases among sixty-three operative cases were noted. The last half of 1917 gave but one malignancy in forty-seven operations on the gallbladder. In thirteen operative cases of general abdominal carcinomatosis, in which the primary focus could not be demonstrated positively the point of greatest involvement was in the neighborhood of the gallbladder. In a total of 1,903 patients operated on, malignant disease of all kinds, excluding the lip epithelioma, was found 285 times. Fifteen of these were of the gallbladder; forty-three of the stomach; sixty-seven of the breast; cecum, twelve; colon and sigmoid, twenty-eight; rectum and recto-sigmoid, twenty-nine; not specifically classified, seventy-nine. This group includes the uterus, kidney, larynx, tongue, liver, thyroid and other organs. The ages of the gallbladder patients varied from 42 to 67. The patients were all females.

Abnormalities of Vertebral Artery.—Two of the forty cases examined by Canizares showed abnormalities in origin of the vertebral artery; and fifteen, in point of entrance to the foramen transversarium. The findings confirm those of Bean and Thane with regard to the greater frequency of abnormalities of origin of the vertebral artery on the left side. Cases of unilateral variations in the point of entrance were almost twice as numerous as the bilateral ones.

Causes of Rancidity of Coconut Oil.—Two-year storage tests were made by Perkins on thirty samples of edible coconut oil. The results were in general agreement with the accepted views of rancidity and its causes. The action of light was found to be a powerful, but not necessary, factor in the production of rancidity. Enzymes from the fresh coconut meat had some effect on the keeping qualities of the oil, but sterilization was of doubtful benefit. An oil of low initial acidity remained sweet during two years' exposure to air and light. The measurement of rancidity is discussed briefly.

*Case of Acute Mania Associated with *Plasmodium Vivax* Infection. F. G. Haughwout, P. T. Lantin and R. Fernandez.—p. 563.

***Plasmodium Vivax* Infection in Acute Mania.**—In the case cited by Haughwout and his associates, infection with *Plasmodium vivax* was associated with cerebral symptoms and death. Parasites were present in the peripheral circulation in small numbers only, and the temperature of the patient at no time rose higher than 39 C., that point being reached a few hours before death. Prior to that time the temperature did not rise above 38 C., this elevation coming several days after the onset of an acute mania. The patient was one of a series of cases that was being experimentally treated with roentgen rays for splenomegaly of malarial origin. He received only one irradiation, and that eight days before the development of the mental disturbance which ran its course and terminated in death eight days following its onset. At no time did the patient show any indication of injury that it seemed possible to trace to the roentgen rays, and the necropsy failed to reveal any such evidence. Microscopic examinations of the feces revealed an infection with

Ancylostoma duodenale. The urine was normal. *Plasmodium vivax* was found in the blood later. On the day of the development of the first mental symptoms an unmistakable trophozoite of *Plasmodium vivax* was found in the blood. The number of parasites in the peripheral blood increased somewhat until from four to six could be counted in 100 oil immersion fields. All were characteristic trophozoites of *Plasmodium vivax*. The patient, who had been receiving iron, quinin, and strychnin up to the time his mania developed, was put on intramuscular injections of quinin and urea, but he failed to show the slightest beneficial effects from them, except for the disappearance of the parasites from the peripheral blood. Twenty-four hours before death epinephrin was administered in the hope of forcing the parasites out of the spleen and into the circulation, but without success. The day before death, the differential leukocyte count showed 78 per cent. polymorphonuclear neutrophils, 7 per cent. lymphocytes, 14 per cent. large mononuclear leukocytes, and 1 per cent. eosinophils. The patient gave no history of previous attacks of mania, and the necropsy failed to disclose any evidence of syphilis. No Wassermann test was made.

Novarsenobillon and Mercury Intravenously. R. Johnson.—p. 436.

Ectopic Ovarian Cyst. J. W. Thomson.—p. 437.

Aortic Endocarditis and Aortitis.—MacIlwaine describes two specimens from two men who both exhibited the classical clinical appearance of aortic regurgitation. The first man died through the rupture of an acute aortic ulcer into the trachea, while the second died after a period of cardiac incompetence which lasted for a considerable time. These two cases occurred in a series of twelve pensioners in hospital who suffered from aortic endocarditis with aortic reflux.

Serotherapy of Cerebrospinal Fever.—Munro used a pooled serum containing 50 per cent. of antibodies to Type 2, and monotypical serum was used after the type was determined. Typing of the cases as they came showed something like 40 per cent. to be Type 1, 42 per cent. to be Type 2, 16 per cent. to be Type 3, and 2 per cent. to be Type 4. To add antibodies of Type 3 and Type 4 to such a pooled serum would reduce its value by from 50 to 82 per cent. of the total cases. Twelve consecutive cases of cerebrospinal fever have come to Munro's notice and no patient has died where it was possible to treat by monotypical serum.

Association of Lethargy and Influenza Bacillus.—Crofton records the histories of four patients treated with pure influenza antigen with good success. For example, in one case, on the chance that the infection might be caused by the influenza bacillus (the case occurred during the epidemic), the patient was given subcutaneously 2½ million pure influenza antigen. The improvement was marked at the end of twelve hours. Thirty-six hours later he was given 5 million, and forty-eight hours later 7½ million. After this he had

complete control of his functions and he was no longer lethargic, although his memory was still defective. He still had difficulty in reading, and his temperature was not quite normal—99 F. He then received 10 million in the morning, forty-eight hours after the last dose; that evening his lethargic symptoms returned in full intensity, although there was no further rise in temperature. His mind did not become normal again in two days. He made a rapid convalescence, but could not read for any length of time or study for some months.

Appendicitis Without Rigidity of Abdominal Muscles.—In two cases seen by Malcolm this sign was absent, and, therefore, he did not regard the cases as being appendicitis. In one case, when the abdomen was opened, the appendix, except about one-half inch at its base, was firmly adherent in a peritoneal pouch behind the cecum. It was removed and recovery was uncomplicated. This patient had her first attack of appendicitis in childhood. The absence of protective contraction of the muscles was due to the position of the appendix and to the fact that a spreading peritonitis was prevented by the adhesions, which had long existed.

Treatment of Gonorrhea in Women.—In these cases Foss makes use of methylene blue as a bactericidal agent, partly for its great affinity for the gonococcus and partly because the anilins are absorbed by mucous membranes and even by squamous epithelium: methylene blue, 1 gm.; glycerin, 25 c.c.; water, ad 100 c.c.. In acute and chronic cases the cervix is swabbed with a saturated solution of sodium bicarbonate in order to remove mucus and discharge. A gauze plug, 12 inches square, is dipped for half its length in the solution; this end is packed tightly against the cervix, the rest lightly in the vagina. The plug is removed after twenty-four hours. This is carried out for five days and then for two days dry plugs are used. This rotation is continued as long as the discharge occurs. There are two contraindications for the use of this method: pregnancy and the puerperal state. General treatment is carried out on the usual lines. Urinary antiseptics and gonococcal vaccine are given as indicated.

Cultivation of Actinomyces.—According to Gordon, the actinomyces fungus can readily be cultivated in ordinary nutrient broth to which a few drops of fresh human blood have been added. It is advisable to sow the material in two broths, one of which is covered by a layer of oil 1 cm. deep. After incubation for a few days at 37 C., the actinomyces fungus can be seen growing at the foot of the tube in small white masses like little puffs. As a rule, growth occurs first in the broth covered with oil, but when other bacteria are present the actinomyces may come up first in the aerobic tube. The practical advantage of getting a growth is that a vaccine can then be prepared. In two cases in which a vaccine of the homologous organism was employed improvement resulted. In the majority of the cases, however, vaccine treatment was not attempted, as secondary infections were present and the disease was too far advanced. Vaccination with a stock actinomyces vaccine is, in Gordon's experience, useless; it seems essential to employ the actual strain infecting the patient.

Acute Edema of Lung.—Brown claims that this condition is allied to angioneurotic edema and is caused by a sudden and temporary dilation of the left ventricle, including the auriculoventricular orifice and consequent acute regurgitation and engorgement of the pulmonary capillaries. It is generally associated with high arterial tension and valvular disease.

Acute Edema of Lungs. C. Musgrave.—p. 468.

Chronology of Beriberi Symptoms.—Hepburn undertook to analyze the early manifestations of beriberi, with a view of establishing the correct chronological order of the early signs and symptoms. Data were compiled from over 300

examinations of 100 cases. All patients were adult Siamese males, and each one was thoroughly examined at least twice. The first symptom or sign to be noted by the patient was invariably one of the three following: (a) edema of feet and legs (50 per cent.); (b) numbness or anesthesia of feet (43 per cent.); and (c) epigastric fullness and distress (7 per cent.). In every case the edema appeared first in the feet, then in the legs, and then in the hands. Appreciable swelling of the hands was seldom seen in these early cases. Practically all patients complained of more or less general weakness. Several patients stated that swelling of the feet had come and gone before the onset of anesthesia. Cardiac enlargement was found at the first examination in only 15 per cent. of cases. Subsequent enlargement occurred in four additional cases in spite of treatment. The treatment adopted was physical rest, with a diet rich in antiberiberi vitamins, polished rice being rigidly excluded. Further treatment was largely symptomatic. A soft mitral systolic murmur was heard at the first examination in twenty cases. Cardiac arrhythmia was noted in five of these early cases.

Strangulated Umbilical Hernia.—A successful resection of a gangrenous ileum is reported by Kennedy. The patient had an umbilical hernia.

Case of Cervical Caries Simulating Cerebellar Tumor. R. R. Armstrong.—p. 499.

Treatment of Ulcerative Colitis.—The best treatment of this condition, Lockhart-Mummery says is by frequent washing through with saline solution after an appendicostomy opening has been established. The operation should be performed as soon as a diagnosis has been made and not left as a last resort, although it may sometimes succeed even then. The diagnosis should always be confirmed by sigmoidoscopy.

Acoustic Nerve Tumor.—In the cases cited by Ward, the disease was present in members of three generations. Full details are given.

Fibroids Complicating Pregnancy.—Stawell's patient was 4½ months pregnant. Troublesome vomiting for two days, constipation and sharp abdominal pain led to operation. Subtotal hysterectomy was performed. On section the ordinary appearance of myoma was seen, no "red degeneration" being observed. The patient made an uninterrupted recovery.

Abdominal Emergencies.—Saint emphasizes that all surgical emergencies should be treated in a properly equipped hospital, and every patient with a more than ordinary abdominal illness should be sent to such a hospital at once for observation and, if necessary, operation.

Delayed Arsenical Poisoning Following Use of Arsphenamin.—Fifty-eight cases of delayed arsenical poisoning following the use of arsphenamin preparations are reported by Strathy and his associates. Eight of these were fatal, being the first of the series to come under observation. The remaining fifty patients made a slow but otherwise

satisfactory convalescence. The greatest number of doses of arsphenamin given in the fatal cases was eleven, the least four. The greatest amount administered, where it was possible to obtain records, was 6.95 gm., the least amount 2.2 gm. The average time of onset of symptoms after the last dose was forty-one days, the longest interval forty-eight days, the shortest eighteen days. The symptoms in every case were similar. The jaundice on onset was rapidly followed by nausea, epigastric pain, stupor, hematemesis, delirium and death. Four of the patients were wildly delirious. In all cases tested the urine contained bile, and in nearly all cases albumin as well. The blood picture was not characteristic. The hemoglobin and red cells were not much reduced. The leukocytes varied in number from 14,000 to 34,000 per cubic millimeter, and the polymorphonuclear leukocytes from 50 to 80 per cent. The greatest number of doses of arsphenamin given in the nonfatal cases was fourteen, the least two. The average time of onset of symptoms was forty-five days, the longest interval 180 days, the shortest three days. Thirty-nine of the patients were admitted for jaundice, eight for dermatitis, two for nephritis, and one for general debility. Jaundice followed dermatitis in one patient, and two other cases of dermatitis were followed by peripheral neuritis. Coated tongue, poor appetite, epigastric distress, abdominal distension, headache, general malaise, and loss of weight were noted throughout the group. Albuminuria was present in twenty-eight cases, bile salts in thirty-five cases, increased urobilin and urobilinogen in sixteen cases, leucin and tyrosin were never found. Jaundice was present in all of the fatal group and thirty-nine of the nonfatal group.

After-History of Tuberculosis Patients.—The points on which Collins lays emphasis are: That pulmonary tuberculosis may be cured if treated in its early stages. It is only the early case that derives any permanent benefit from sanatorium treatment (with rare exceptions); hence the futility of clogging the sanatoriums with the more advanced type of case. Much more strenuous preventive measures should be adopted—e. g., additional suitable open air schools and institutions for very advanced cases. There is a sad lack of suitable institutions for the tuberculous child.

Intestinal Obstruction.—The cases reported by Forsyth are: acute angulation at the hepatic flexure from pericolicitis; rupture of the teniae coli of the cecum; polyp of the ileum accompanied by chronic intussusception; acute intestinal obstruction from traction diverticulum of the ileum; strangulation of a loop of ileum by an adherent appendix epiploica of the sigmoid.

Combined Aortic and Mitral Regurgitation.—The most outstanding feature in Gordon's case was its duration—thirty years. Points to which attention is drawn are: the case was uncomplicatedly rheumatic, dating from a single attack of acute rheumatism at 22; the patient was otherwise healthy, with no lung or kidney complications, for the most part her work was free from physical strain; she successfully avoided further rheumatism; the degree of aortic regurgitation was probably slight for a good many years, since "water-hammer" pulse and pulsation in the neck were absent for that time (remembering, however, the influence of coincident mitral regurgitation in modifying the pulse); precordial pain, palpitation and dyspnea on exertion, with occasional faintness, were present almost throughout; so long as eleven years before her death the apex beat, in the erect position, was already in the sixth space, and 1 inch outside the left mammary line.

Dental Infection as Cause of Iritis.—Pockley claims that in over thirty years' practice as chief of the ophthalmic department of the largest general hospital in Australia and a considerable private practice and, though of late years he has

been on the lookout for dental troubles and other focal infections as a cause, and has got advice and treatment in all doubtful cases from dentists and physicians, he has rarely, if ever, met with a case in which he could satisfy himself that the teeth were the cause of iritis. Excluding syphilitic, gonorrheal, tubercular, sympathetic and a few other cases of iritis, for which a probable cause or association can be found, his experience is that most, in fact nearly all the patients showed benefit or cure by the proper use of salicylates combined with appropriate local ocular treatment. Operation may, of course, be required in old standing or recurring cases.

Carcinomatous Pericarditis.—A man, aged 49 years, was found dead in bed. He had had a swelling behind the right angle of his jaw, which had caused him a good deal of pain, but for which he had not consulted any doctor. At the post-mortem examination, a hard swelling was noticed in the region of the right parotid gland. It was not further examined. The pericardial sac was distended, with a large quantity of bloodstained fluid, a chronic pericarditis being present. The left lung was adherent throughout. The gastric veins were prominent, the liver had the appearance of nutmeg and the kidneys showed advanced chronic interstitial nephritis. Death was attributed to chronic interstitial nephritis and chronic pericarditis. On macroscopic examination the surface of the heart showed a slight fibrous pericarditis, while in the neighborhood of the auricles were discrete, minute, nodular projections. On section, the pericardial surface of the heart showed here and there narrow, whitish, pencil-like thickenings. When microscopic sections were cut, Cleland and Palmer found among granulation tissue in places an extensive infiltration by deposits of carcinoma cells in a reticulum.

Educational Number.

Relation Between Brain and Liver in Epilepsy.—The records of postmortem examinations of twenty-five cases of epilepsy, as far as the liver, etc., is concerned are given by Lalor and Haddow. The summary of their observations is that the brain-liver ratio is 35:33. The normal ratio was brain to liver, 12:15, so that the conditions are entirely reversed in the epileptic condition. The percentage in which the weights of the brain exceed those of the liver was 80 in the twenty-five cases examined. In 24 per cent. of cases status epilepticus was found and associated with this condition was toughness and congestion, indicating previous chronic irritation and present acute inflammation in 30 per cent. of these cases. There were signs of disease of the gallbladder and possibly of chronic intoxication from this source. In 8 per cent. of cases the mesenteric glands were enlarged, indicating some chronic intestinal toxemia of fairly long duration. In 20 per cent. of cases there was definite trouble in the gallbladder tract. In 40 per cent. of cases there was evidence of chronic hepatic irritation, indicative of a continuous and slow toxin, displayed by fibrosis or toxic or fatty changes. In 8 per cent. of cases there is distinct evidence of a chronic intestinal intoxication, which might in all probability be obviated by treatment.

First Case of Contagion of Oriental Sore in France. P. Ravaut.—p. 198.

Experimental Hematology.—Normet reports experiments on rabbits and guinea-pigs after injection of sodium citrate; this allows the study of the blood to be continued in vitro. His illustrations demonstrate, he asserts, the course of the evolution of the blood corpuscle, the mononuclear leukocyte being capable of producing directly or indirectly, as he explains, the eosinophils and the erythrocytes. He regards it as the generator of all the blood cells. The budding or gemmation which he describes as the origin of the hematoblasts, shows a process of cell reproduction which was not suspected in metazoa, and which he is now studying in other tissues besides the blood.

Quadruple Birth.—The woman had borne six normal children when in 1915 she gave birth to two boys and two girls at one time, and all are in good health to date. There was no history of twins in either family before.

Percussion Locates Painful Points in the Abdomen.—Hayem strikes with the middle finger, like a hammer, and has found that this locates the tender points with greater precision than mere pressure alone. Lately he has been using special hammers, with a spring, for the purpose. This hammer technic may reveal points of tenderness which escape detection by ordinary palpation and pressure. The pain elicited is usually visceral, and with dyspepsia, it is generally in the liver. With chronic stomach disease, aside from ulcer and cancer, this *martelage* often elicits pain in the liver and intestine.

Sulphur in the Cancerous Liver.—Robin concludes from his long study of sulphur metabolism in malignant disease that there must be some special proteolytic ferment in the organ or part of the organ in which cancer develops which prepares the soil for the malignant disease. Research in this line may throw light on chemotherapy of cancer. The sulphur content was much below normal in the cancer regions in five cancerous livers examined.

Bulletins de la Société Médicale des Hôpitaux, Paris

*Epidemic Encephalitis. Harvier and others.—p. 179.

Gangrenous Process in Lung; Recovery under Antigangrene Serotherapy. H. Dufour and others.—p. 190.

Acute Encephalitis in Children.—Comby warns that acute encephalitis is frequent in children but is usually mistaken for tuberculous meningitis until lumbar puncture shows the absence of lymphocytosis. In his twenty-five cases published in 1907 the lethargic type was manifest in about a third of the cases. The encephalitis developed secondary to influenza, whooping cough, vaccination, enteritis or gas poisoning in the majority, but in some the disease seemed to be primary. Some of the children died and some recovered completely, but others were left with grave sequelae.

Neurofibromatosis.—Chauffard and Brodin report a case which apparently confirms the connection between Recklinghausen's disease and the suprarenals. Suprarenal treatment was followed by immediate and notable improvement, as in Pic's and Jullien's two cases.

Malarial Attacks Masquerading as Tetany.—Hébert and Bloch report a case in which attacks of tetany every second day were finally explained by finding *Plasmodium vivax* in the blood. With tetany from any cause, they suggest that it might be well to examine for parasites. The attacks in this case resembled the hemoclastic crises from chilling to which Widal and others have called attention in paroxysmal hemoglobinuria.

Azotemia with Pulsus Alternans.—Esmein and Heitz tabulate the details of twenty-five cases of pulsus alternans showing the high urea content of the blood; it ranged from 0.43 to 1.66 gm. per liter. After the intake of meat was restricted, marked improvement followed. These experiences testify to the importance of putting patients with pulsus alternans on a nitrogen-poor diet in addition to heart tonics and diuretics. The subject is timely, they add, as pulsus alternans seems to be increasing in frequency; forty cases have been encountered by them in the last few years. The possibility of syphilis as a causal factor must not be forgotten. In the discussion that followed, Josué suggested that the azotemia in these cases may have been merely relative, depending on oliguria. The alternating pulse is a sign of weakness of the heart, and this in turn may entail oliguria and secondary azotemia even when the kidneys are sound. Heart tonics may transform the whole clinical picture.

Epidemic Encephalitis.—Netter estimates at 500 the recent cases of lethargic encephalitis at Paris. Other speakers commented on the variety of forms the disease is now assuming, even walking cases. Labbé and Hutinel report a case with lymphocytosis and excessive amounts of glucose in the lumbar puncture fluid. Others report series of cases with delirium and hallucinations. Morax and others discuss the ocular symptoms, and Weil describes a case with symptoms indicating involvement of the spinal cord.

Lyon Médical

April 10, 1920, 129, No. 7

*Tuberculous Rheumatism. L. Duvernay.—p. 298.

Tuberculous Rheumatism.—Duvernay states that while the existence of tuberculous rheumatism is quite generally recognized, there are many erroneous ideas afloat in regard to the nature of the disease and with respect to its treatment. Many seem to think of tuberculous rheumatism as an articular localization of the Koch bacillus, which Duvernay says is not only still unproved but seems to be in contradiction with almost all the facts. It should therefore be emphasized that tuberculous rheumatism (or inflammatory tuberculosis) presents just ordinary lesions, and that there are no evidences of classic tuberculosis. He regards tuberculous rheumatism as not so much a toxic rheumatism as an antitoxic or reactional rheumatism. It seldom appears when the toxic substances are abundant. The tuberculous rheumatic is one who has recovered from tuberculosis, whose organism is defending itself, and in whom the antibodies are very active and very abundant. Since tuberculous rheumatism is not a local tuberculosis but a rheumatism, it should be treated like other forms of rheumatism: warmth, immobilization, during the acute stages but mobilization and massage as early as possible to avoid atrophy and ankylosis.

Presse Médicale, Paris

*Angina Pectoris. A. Martinet.—p. 153.

*Bismuth Poisoning. C. D. Constantinescu and A. Jonescu.—p. 155.

Ocular Ataxia in Tabes. A. Cantonnet.—p. 156.

Angina Pectoris.—Martinet seeks for and applies treatment for the anatomic elements responsible in aorta, coronaries and myocardium; for the pathologic physiology in the nerves around the aorta, ischemia in the myocardium, and cardiac insufficiency; for the etiologic elements, syphilis, gout, rheumatism, arteriosclerosis, obesity or neuropathies, and, finally, for the provocative elements, such as overexertion, emotional stress, excesses, meteorism or aerophagia. During a severe attack he injects atropin and morphin in one thigh and camphorated oil in the other, and wraps the chest in a compress wrung out of mustard water, 2 handfuls of mustard in 2 liters of very hot water; covers with oiled silk and keeps it on until the skin is bright red (usually from fifteen to thirty minutes); or the arms can be held in very hot water; when there is danger of acute edema of the lung, blood-letting at the elbow. Besides these and other measures described, he lays great stress on tranquilizing the patient. The anguish and fear maintain or start further spasms of the vessels.

and one of the main points in treatment is to reassure the patient, telling him that the gravity of angina pectoris has been much exaggerated, and that many persons subject to it long survive, with ordinary care. When aerophagia is a prominent element, it is easy to convince the patient that the disturbances are not induced or aggravated by muscular exertion, as a rule. A stimulant might be prescribed, to be carried habitually, a few swallows to be taken when symptoms suggest an impending attack. He usually orders for this "gri-gri," as he calls it, a little ammonium acetate in brandy and syrup.

Severe Bismuth Poisoning.—The bismuth had been given in the case reported for roentgen examination with supposed gastric ulcer. The blood showed nitrites but no trace of bismuth, and the symptoms and spectrum indicated that the oxyhemoglobin had been transformed into reduced hemoglobin and what he calls oxy-azotic hemoglobin.

*Pathogenesis of Cholera. G. Sanarelli.—p. 797.

*Sterilization of Drinking Water. D. De Blasi.—p. 842.

Agglutins for Proteus X in the Serum of Typhus Patients. Levi Della Vida.—p. 847.

Pathogenesis of Cholera.—In this first of a series of articles on this subject Sanarelli describes research on animals to study the natural defences of the peritoneum against the cholera vibrios.

Sterilization of Drinking Water.—Among the chemicals investigated by De Blasi he found silver fluorid most effectual, but it required a comparatively strong solution and contact of an hour to completely sterilize the water. The water is rendered limpid afterward by addition of sodium thiosulphate. Cattle and horses drink water containing up to 1:10,000 of the silver fluorid (*tachiolio*) without reluctance or apparent harm, he adds. His research with sodium hypochlorite and certain other chemicals merely confirms what others have published.

Organic and Functional Anesthesia. G. Dragotti.—p. 327.

Donato Rossetti, 1667, a Pioneer in the Study of the Senses. G. Bilancioni.—p. 338.

Medical Treatment of Dysenteric Liver Abscess.—The symptoms indicated amebic dysentery of several months' standing but no amebas could be cultivated from the stools nor from the thick, chocolate colored fluid obtained by simple puncture of the enlarged right lobe of the liver through the sixth interspace on the axillary line. The liver was not tender and the spleen was not enlarged. Under a vigorous course of subcutaneous injections of emetin, the fever and other symptoms promptly subsided to complete clinical recovery, confirming the presumptive diagnosis, and establishing anew the efficacy of medical treatment alone with amebic liver abscess.

*Spasm of Walls of Arteries. E. Morelli.—p. 355.

Vaginal Eucleation of Submucosa Uterine Fibroma. C. R. Belgrano.—p. 358.

Arterial Spasm with Hypertension.—Morelli emphasizes that in estimating the arterial blood pressure it is necessary to take into account the sphygmogram as well as measure the systolic and diastolic pressure. Forlanini regarded essential arteriospasm as a morbid entity, the abnormal irritability of the muscular walls of the arteries an expression of pathologic conditions apart from arteriosclerosis. The sphygmogram may vary widely in persons whose blood pressure measurements show the same figures. De Giovanni noted that after palpation of the radial artery the area

palpated remained contracted for a time, testifying to the excitability of the artery walls. Zoja has also called attention to the changes in the sphygmogram when the nerves in the arm above are irritated by stroking them across. Their tests were made on persons with normal blood pressure, but Morelli found the response even more pronounced with high pressure. The spasmodic contraction may be in the medium sized arteries or in the terminal arterioles, or in both. The effect is much like that of arteriosclerosis; the contracted artery may feel as hard and rigid as with sclerosis, but differentiation is extremely important as the treatment for one may be injurious in the other. When the medium arteries alone are contracted, the arterioles below and the circulation suffer, and the arterial pressure from extremely high during systole drops to extremely low during diastole. With this tendency to spasm of the arteries, the tonus of the arteries may respond more rapidly and intensely to stimuli of different kinds than has as yet been demonstrated with normal arteries. The spasm may be total or segmentary, and the type may differ as it occurs during systole or diastole; the increase in the diastolic tonus of the artery preventing the stretching of the artery during the diastole. The combination of spasm of the arteriole with spasm of the larger artery throws much extra work on the heart and essentially disturbs the circulation.

*Motor Plastic Operations: Cinematization. A. Pellegrini.—p. 1113.

*Pleuritis with Liver Disease. A. Furno.—p. 1122.

Motor Plastic Operations.—Pellegrini here presents the report for 1918 and 1919 of what has been accomplished in Italy in the line of cinematization, cineplastics and cineprosthetic appliances. Among the twenty-one illustrations some show the technic and results of a tunnel made in the place where the shoulder had been enucleated. This tunnel allows a grasp of an instrument and motor control to a certain extent, backed by the strength of the shoulder muscles. The Zerlini artificial hand can be used both with simple motor loops of muscles and alternating loops. Some of the illustrations show a man after amputation of the arm writing with this Zerlini hand, or pouring from a bottle, or holding up a cane-seated chair. The principles and construction of this artificial hand are described and its simplicity emphasized.

Metahepatic Pleurisy.—Furno explains that four fifths of the lymphatics which originate in the liver pass into the pleural cavity above, and line the parietal and visceral sheets of the pleura. These lymphatics are the only ones that enter the pleura from the abdominal cavity, and this readily explains why pleuritis with or without effusion is often an important aid in the diagnosis of liver disease. In none of the other viscera are pathologic conditions accompanied by pleuritis in this way. He relates some cases in which the febrile pleuritis was treated on a mistaken basis for about two years before the causal liver disease was suspected. This mistake is particularly disastrous when the liver disease is of syphilitic origin. Irreparable lesions may become installed as the years pass without proper treatment while attention is focused exclusively on the pleura. Furno knows of six cases at least in which the patients had been sent to a sanatorium for treatment of the supposed tuberculosis. In other cases, operations for gallstones had been done, but on suspicion of a syphilitic origin all recovered promptly under mercury. Pleuritis with chills, fever and night sweats should suggest the liver first of all. The liver is often silent in its pathology, he says, or symptoms from it simulate those from other viscera; right pleuritis may be the first thing to give the clue.

*Constitutional Anomalies and Syringomyelia. A. Finzi.—p. 199.

*Chilling of the Skin in Relation to Disease of the Respiratory Apparatus. G. Galeotti.—p. 205.

Constitutional Anomalies in Relation to Syringomyelia.—Finzi recalls some cases on record in which four of the five

children in a family or the mother and three children all presented syringomyelia, and states that the twenty-one patients with syringomyelia he has recently examined all presented an unusual number of malformations or other constitutional anomalies. They are so frequent and so universal that a casual coincidence can be excluded. An inherited neuropathic taint is particularly common, and any organ is liable to display the congenital anomalies.

Chilling of the Skin in Relation to Disease of the Respiratory Apparatus.—Galeotti reviews the conflicting theoretical testimony in this line in contrast to the empiric certainty of the pathogenic action on the air passages of chilling of the body. He then describes research by himself, Azzi, Viale and others which demonstrated that the temperature of the expired air does not correspond to the blood temperature, but to the temperature of the skin at the moment. It was found that when the vessels in the skin had become constricted under the influence of cold, the expired air was proportionately cooler, and it grew warmer as the vessels in the skin dilated under the influence of warmth. Their findings can mean only that there is a close nervous connection between the vessels in the skin and the vessels in the air passages. As one system contracts, those in the other contract instantaneously with them, and they dilate in the same way. The temperature of the air in the lungs is determined by the blood in the vessels, and if these vessels contract, the expired air is cooler than when the vessels are dilated. Sudden vasoconstriction in the lungs may favor infection from saprophytes by checking phagocytosis or by the altered metabolism or by the paralytic dilatation which follows the vasoconstriction. The hyperemia in the vessels of the air passages which accompanies hyperemia, from revulsion to the skin, in the vessels of the skin, explains, he says, the benefit from revulsion and fomentations applied to the chest, while the reverse mechanism explains the benefit from ice applied to the skin in arresting hemoptysis. He explains in conclusion that this behavior of the vessels in the air passages seems to be an atavistic functional relic of the primitive thermo-regulating mechanism, analogous to what is observed in dogs.

Pituitary Tumors with Unusual Clinical Picture.—Reichmann reports two cases in which the symptoms had suggested exophthalmic goiter, tendency to acromegaly, suprarenal disease, and disease of the genital glands, but necropsy revealed in the woman of 36 an eosinophil adenoma in the pituitary, and in the man of 51 the roentgen findings seem to indicate a similar tumor. The face was red and puffy in both; the exophthalmos was pronounced but the thyroid was not enlarged, and the pulse was slow, with extreme weakness of muscles, emaciation, edema of the legs, slight glycosuria, no albuminuria, and no signs of contracted kidney, but the blood pressure was very high, and there was pronounced osteoporosis of the spine. The symptoms thus indicated excessive functioning of the pituitary and suprarenals, with thyroid deficiency. The curvature of the spine from the osteoporosis was evidently responsible for the severe neuralgiform pains in the back in the woman's case. Tests for epinephrin in her blood were negative, but the blood pressure of 200 mm. mercury pointed to the suprarenals, and as the pains in the back were unbearable, Reichmann yielded to the patient's demand for operative relief, and removed the left suprarenal. The woman died nine days later from peritonitis, nearly three years from the first onset of symptoms, which had been edema of the legs, exophthalmos and arrest of menstruation. The latter had never been constantly regular.

Scurvy.—Bierich as chief of the Russian Red Cross central scurvy station was able to compile data in regard to 1,343 cases with necropsy findings in six cases. He says that before the outbreak of the revolution in Russia, fully 98 per cent. of the scurvy patients were promptly cured by the usual antiscorbutic diet, but after the onset of the revolution only from 20 to 30 per cent. could be cured although the men's food was much better. There were whole divisions of troops in which 75 per cent. developed scurvy. These and other facts observed testify, he says, that the endogenous factors in the disease are racial and mental; the exogenous are the deficient diet. The injury seems to affect primarily the endothelium of the capillaries, the normal structure of which is reversibly injured by the lack of some nitrogen-containing building-stone indispensable for its specific function. The insufficiency of the blood-producing organs seems to be secondary to this structural damage to the capillaries. Treatment in many of his cases had to include psychotherapy, transfusion of citrated blood and splints, in addition to the usual dietetic measures.

The Range of Resisting Power of the Erythrocytes.—Bauer and Aschner recall that sometimes the concentration of the substance causing the first sign of laking may be very close to the concentration causing total hemolysis. In other cases there may be a wide range between them. This "resistance range" is the expression of the biologic difference between erythrocytes which from other standpoints seem to be identical in every respect. They found the widest range in severe anemia, especially the anemia with chronic Bright's disease; the smallest range was in tuberculosis with a mild course, and injections of tuberculin seemed to increase the resisting power of the erythrocytes. They tested with solutions of sodium chlorid ranging from 0.6 per cent. to 0.3 per cent., drawing the blood first into a solution of 0.28 parts potassium oxalate and 0.8 parts sodium chlorid in 100 parts distilled water and centrifuging, then making the suspension of the erythrocytes in 0.9 per cent. sodium chlorid solution. The set of test tubes was compared with a colorimeter scale (hemoglobin solution). The younger erythrocytes were the more resistant. The resistance range varied in the same person at different times in their tests of 100 persons. The findings are tabulated and a theoretical explanation tentatively advanced.

Hypertrophic Pulmonary Osteo-Arthropathy.—In Hoffmann's first case the woman of 40 developed drumstick fingers and thickening of the periosteum of different bones about six months after the clinical cure of uterine cancer under mesothorium treatment. A year after the development of the typical *osteoarthropathie hypertrophique pneumique*, pains and ataxia in the legs testified to neuritis. Shadows in the lungs seem to be metastases of the cancer, but they have not progressed during the year the woman has been under observation. In a second case, in a man of 30, the osteoarthropathy was secondary to bronchiectasia with foci of gangrene. No instance of primary osteoarthropathy of this Marie type has yet come to necropsy, to Hoffmann's knowledge. He remarks that the relations between the primary form and the secondary toxigenous form are not at all certain.

The Heart Action During Sleep.—Klewitz has been taking electrocardiograms of twenty-five persons during sleep, including a number of healthy subjects, eight with well compensated valvular disease, three with failing compensation and two with tachycardia or bradycardia after influenza. The electrocardiogram in sleep often differed materially from the electrocardiogram of the same subject awake. In the healthy, the heart cycle was lengthened, sometimes up to one tenth. The ventricle systole was prolonged more in proportion than the auricle systole. The differences in heart action during sleep are advantageous for the circulation as a whole. With the different forms of heart disease no regularity in the sleep changes could be detected. In the one case of bradycardia the heart cycle was shortened.

Test Pressure on the Vagus.—Kleemann applied to 127 patients Czermak's test pressure on the vagus, and the response was studied with electrocardiography. In 80 of

150 tests of the right vagus no effect was apparent, as also in 90 of 149 tests of the left vagus. As a rule, pronounced modification from the pressure was evident only in cases of heart disease, but the intensity of the response was not proportional to the severity of the latter, and a positive response did not always occur with heart disease. The findings were interesting with partial heart block, namely, its aggravation, and the development of a regular auricle-ventricle rhythm while the rate of sinus conduction was reduced.

Results of Surgical Treatment of Nephritis Under War and Peace Conditions.—Kümmell holds that acute nephritis with abscesses should be treated by means of nephrotomy or decapsulation as soon as the diagnosis has been definitely made, as he has found the results very favorable. The form of chronic nephritis whose predominant symptom is pain in the kidney (mostly unilateral), nephritis dolorosa, is favorably influenced by decapsulation, and the patients remain free from symptoms, able to work and to all appearances perfectly well. In the case of unilateral partial nephritis, if internal treatment fails to give relief, operative intervention should not be postponed too long, lest the diseased area should increase or the other kidney should become involved. Chronic hemorrhagic nephritis, whose predominant symptom is hemorrhage, more or less profuse, usually unilateral, and which often simulates the presence of tumors, reacts most favorably to decapsulation. The hemorrhages almost always cease and seldom reappear. The patients remain free from symptoms for long periods and are able to work.

Compulsory Antityphoid Vaccination of Civilian Population.—Basten has investigated the results of the extensive vaccination of civilians against typhoid undertaken by the British army in December, 1918, during the occupation of German territory. Civilians between the ages of 6 and 45 were compelled in certain districts during a typhoid epidemic to accept vaccination unless there were certain contraindications, such as advanced pregnancy, recent childbirth, advanced tuberculosis, etc. Basten draws these conclusions from his investigations: 1. The vaccination was accomplished without any injury to the health of any age group. 2. No unfavorable influence on pregnancy or on lactation in nursing mothers could be noted. 3. The English vaccine, which contained also paratyphoid A and B strains, did not cause more severe reactions than the German vaccine which contained only typhoid strains. 4. The vaccination checked successfully many cases of typhoid that were in the incubation stage and thus rid the population of the infection. 5. No influence from the vaccination on the typhoid morbidity percentage among the vaccinated as compared with the unvaccinated, during the following six months, could be noted, but the vaccination attenuated the disease in the typhoid patients who were vaccinated. Conclusion 5 would

seem to indicate that two injections as given are not sufficient to immunize against the disease, and that three injections are necessary. The experience of the German army has been that three injections are required to establish immunity.

The Medicolegal Significance of the Vagus Pressure Experiment.—Von Teubern states that the Czermak vagus pressure experiment has a certain medicolegal value as it lends support to the view that in persons with a strongly positive vagus response a more or less intensive compression of the throat for even a short space of time, as in choking, attempts to strangle, etc., might be alone sufficient to produce immediate arrest of the heart action.

Splenic Anemia in Young Children.—Aschenheim opposes the tendency to regard splenic anemia as belonging to a subordinate group of the ordinary anemias in infants and young children, and defends the view that it is a clearly defined disease, characterized by a very large spleen, a yellow color of the skin, swelling of the liver, and frequent edemas and hemorrhages.

Treatment of Prolapse of the Rectum in Children.—Plenz opposes the use of the subcutaneous wire ring as recommended by Thiersch in the treatment of prolapse of the rectum in children. It produces severe pain during later defecation and, acting as a foreign body, it leads almost invariably to suppuration and the formation of abscesses. He expresses surprise that since Kirschner called attention to the excellent results obtainable with fascia, so little use has been made of the suggestion. Plenz has used the fascia method in place of the wire ring in six cases, and has been well pleased with the results.

Preventive Vaccination Against Infection.—The experience was with war wounds, but the number of cases (twenty) is too small for definite conclusions. In three of the men the wound became infected. There was no temperature or pulse reaction to the injection of the autovaccine.

Plugging Cavities in Bones.—Roentgenograms are given of seven cases—all war wounds—in which the injected wax or hard paraffin seemed to stimulate the tissues to repair. The foreign substance was expelled as the cavity healed up behind it. In only one of the cases was healing by primary intention realized; the others were suppurating, but they began to expel the foreign substance by the third or fourth week, and the large defect gradually healed up completely, with very little impairment of function. To hasten the healing, in some of the cases the displaced wax was removed.

Arteriovenous Aneurysm.—Zur Verth presents evidence to show the serious damage to the general circulation, liable to result from an arteriovenous aneurysm of large vessels. The heart enlarges and may show signs of weakness, while both heart and vessels are more susceptible to reflex influences.

Intravenous Infusion by the Drop Method.—Friedemann has been applying this method of infusion for seven years, and his experience in several hundreds of cases has proved extremely satisfactory, he says. As the action of epinephrin is fleeting, this continuous drop method is particularly advantageous on this account. He generally uses a 0.9 per cent. solution of sodium chlorid or Ringer's solution, adding epinephrin, glucose or digitalis as may be indicated. A sign that the patient is beginning to get too much fluid is an increased lacrimal secretion or slight edema of the eyelids. On account of the danger of hypostatic pneumonia, he is careful not to infuse too much fluid when there seems to be a predisposition to this. He has never had any case of

embolism with this drop infusion. With menacing hemorrhage, the drop method replaces the losses of blood without abruptly raising the blood pressure. A further special advantage is with exhaustion of all kinds, dehydration of tissues, and as a preliminary to operations on the enfeebled. Since he has been relying on drop infusion he has much widened the limits of operability, patients coming to the table with a fine pulse when other surgeons had declined to operate on account of the weakness and almost imperceptible pulse before. In severe general infections, the combination of drop infusion with venesection has rendered valuable service, as also drop infusion with camphor or epinephrin, with or without venesection, in collapse in pneumonia. He cites typical instances of all these conditions to illustrate the benefit from the drop infusion, as also in the severe headache after intraspinal anesthesia, and in two patients moribund from kidney disease. His extensive bibliography on infusion is all from German writers.

High Sacral Anesthesia.—Schuster analyzes the experiences in 483 cases in which epidural injection of an anesthetic had been applied for major operations of various kinds. The anesthesia was complete in 85.5 per cent. and only 6 per cent. proved refractory. Adding the 155 cases previously published, this gives successful anesthesia in 85.7 per cent. of the total 638 cases. He says that there do not seem to be any absolute contraindications, but particular caution is necessary with severe atherosclerosis, on account of the necessity for raising the pelvis. The special indications for the high sacral or epidural technic are major operations in which inhalation anesthesia is contraindicated and local anesthesia is not practicable. It is applicable for all operations, he says, from the toes to the xiphoid appendix up to the age of 18, and occasionally up to 12 or 13 with 30 c.c. of procain solution. His tabulation includes twenty-three cases of resection of the stomach for cancer; sixteen of cholecystectomy; four of nephrectomy; eight of amputation of the rectum for cancer; one of amputation of the femur, and eleven of resection of the cancerous intestine. The few refractory cases were mostly in the operations on the stomach, intestines or kidneys. There was serious collapse in three extremely feeble patients; one was subject to apoplectiform attacks, which should have warned not to lower the head. The epidural technic in itself was not responsible for the fatality but the lowering of the head entailed fatal cerebral hemorrhage. The two other patients required artificial respiration during the collapse from the epidural injection, done in one case for prostatectomy. The man recovered but succumbed in less than two weeks to his uremia. The other patient had suppurative peritonitis from appendicitis; conditions were so grave that anesthesia of any kind was dangerous. He was brought out of the severe collapse by intravenous infusion of saline plus epinephrin and pituitary, while the measures for artificial respiration were continued. The man died ten hours after conclusion of the operation.

Surgical Treatment of Duodenal Ulcer.—Heymann states that the surgeon will sometimes make a wrong diagnosis of duodenal ulcer, and on opening the abdominal cavity will not only not find the definitely expected ulcer but not even any pathologic changes characteristic of an ulcer. If no adhesions or thickening of the duodenal wall, nor scars on the serosa are found, he opens the anterior wall of not only the horizontal portion of the duodenum, where the ulcer is usually found, but also of the descending portion where it might possibly be located. The ascending portion is left

untouched as no ulcers have been reported as yet in this part. The mucosa is carefully inspected and palpated, and occasionally he introduces a short rectoscope in the peripheral end of the duodenum. If no ulceration is discovered he does not think that a palliative operation such as gastro-enterostomy or Eiselsberg's exclusion of the pylorus, much less resection of the antrum, is indicated, but rather regards the laparotomy as an explorative measure, and merely sutures the duodenum and abdomen. Remarkable benefit may follow the mere exploratory laparotomy. There may, however, be occasions when the removal of the gallbladder or appendix is indicated.

Multiple Benign Sarcoid.—Because of its rarity Stümpke reports a second case of this disease, having reported his first case in 1913. Boeck's sarcoid belongs to the exanthematous forms of tuberculosis of the skin, and was first described by Boeck in 1899. This disease occupies a peculiar position not only on account of its clinical form but also because the methods used to prove its tuberculous nature are so frequently unavailing. That the microscopic picture of Boeck's sarcoid is not absolutely characteristic for the affection, as was asserted by Boeck, has been shown by Lewandowski and others; similar changes occur in other tuberculids, as erythema induratum; also in lupus. The sharply circumscribed foci of epithelioid cells are not found exclusively in Boeck's sarcoid. As regards treatment, we are well nigh powerless. In Stümpke's first case, reported in 1913, he had used tuberculin treatment, whereupon an exacerbation of the lung condition ensued, which resulted in the patient's death. He therefore advises caution in dealing with Boeck's sarcoid, as with all tuberculids. His second case is in a woman of 35, who has been suffering for thirteen years from a stubborn type. The lesions are found mainly on the right and (more recently) on the left cheek, and on the left upper arm. The lymph glands are not involved. All the therapeutic methods tried so far have proved unsuccessful.

Petechial Eruption in Pneumococcus Meningitis.—Hirsch has been unable to find in the literature the description of a single case of petechial exanthem in pneumococcus meningitis, but reports a case in a man of 78. The diagnostic value of hemorrhagic exanthems in connection with the diagnosis of obscure cases of meningitis was learned during the war. Meningitis often appeared in such an atypical form, without the classical symptoms, so that in many cases a definite diagnosis was possible only at necropsy. Many physicians did not know how to interpret the exanthems that were present, and thus, owing to the absence of typical symptoms of epidemic meningitis, they were led to the false diagnosis of typhus fever. In nonepidemic meningitis exanthems are rare. In Hirsch's case the exanthem was entirely different from those occurring in meningococcus meningitis. It was evidently a toxic eruption, and he is dubious whether it was due to the meningitis, which was in the foreground of the clinical picture, or whether it should be laid to the account of the pneumonia.

Fatal Cases of Gas Phlegmon After Caffein Injection.—Schranz adds one more to the growing list of cases in which, following injections of caffein or camphor, a fulminating gas phlegmon developed at the site of the injection and resulted fatally. His case was in a professional nurse of 21. Oct. 21, 1918, she was taken with influenzal pneumonia. The temperature ranged between 38.5 and 39.9 C. (101.3 and 103.8 F.). Owing to the weak heart action she was receiving camphor injections hourly and caffein every four hours. October 25, at 3 p. m., she received (with the same syringe and the same solution as usual) an injection of caffein on the extensor aspect of the left thigh. Half an hour later severe pain set in at the site of the injection. There was a small hemorrhagic spot surrounded by a reddish ring the size of a quarter, painful to the touch. Compresses and immobilization of the limb did not quiet the patient. The pain abated somewhat but did not stop. At 9 p. m. the patient voided about 50 c.c. of urine of a peculiar color, dark brown, with a greenish tinge. It contained albumin and traces of blood. By 10 p. m. the whole thigh, the knee and part of the lower leg were swollen. On palpation the thigh seemed to be full of air bubbles. The color changes of the skin, which became

more and more pronounced, were startling. The thigh was a dirty, yellowish brown, verging at the sides into a bluish red. The thorax, the cheeks and the forehead bore bluish-red spots. The thigh continued to swell during the night, and the abdomen became tympanitic. The general condition of the patient grew worse, death ensuing toward morning. Schranz has been struck by the frequent association of gas phlegmon and influenzal pneumonia, for which he seeks an adequate explanation.

Arrest of Hemorrhagic Purpura by Raying the Spleen.—Stephan reports a case of purpura fulminans in a man of 45 in which a refractory hemorrhagic diathesis was successfully combated early in 1919 by means of deep roentgenotherapy applied to the spleen. Investigations that he undertook in connection with this result lead him to state that roentgen radiation applied to the spleen rapidly decreases the coagulation time of the blood in vitro, and increases likewise to a considerable extent the amount of coagulating ferment in the blood serum. Radiation seems to have the same effect on the organism as extensive loss of blood. The essential factor that arrested and cured the hemorrhagic tendency was the increase in the quantity of the coagulating ferment, and this was realized by the action of the roentgen rays on the spleen. He thinks they exert a specific functional stimulus on the elements of the spleen other than the lymph follicles. The blood platelet count does not seem to be modified. The coagulation time was shortened sometimes to one fourth even in normal subjects by raying the spleen; the maximum effect was apparent between the second and fourth hours, and then gradually subsided. His clinical and experimental research has demonstrated, he announces in conclusion, "that stimulating the functioning of the spleen by roentgen radiant energy must be regarded as theoretically a true physiologic method of arresting venous and parenchymatous hemorrhages. In numerous cases it has proved extraordinarily effectual in practice, far surpassing the effect of any medicinal hemostatics."

Diphtheria Antitoxin in Malignant Influenza. A. van Balen.—p. 795.

The State Commission Appointed to Study the Methods of Unqualified Practitioners.—This is the fourth and last of van Rijnberk's articles commenting on the medical and the legal commissions appointed by the state to study the ways and results of treatment of the sick by the unqualified, to determine whether and how the barriers to practice should be lowered. The reports of the Kwakzalvers-Commissie were recently mentioned in THE JOURNAL, page 1109.

Inguinal Hernia.—Van Dam concludes his analysis of the different methods in vogue for correction of inguinal hernia by commending, for boys, the torsion-ligature method for the indirect or lateral hernia; for girls and women, the Alexander-Adams. For men, he prefers the Breiner or Ferrari method if the muscles are strong and the canal narrow. If the canal is widely gaping and the muscles are strong, the Bassini or Brenner is preferable, possibly supplemented by a small laparotomy. On the other hand, if the muscles are flabby, or their insertion on Poupart's ligament is unusually high, it is advisable to reinforce the transverse fascia with a flap from the anterior sheath of the rectus, doubling the

aponeurosis if it is relaxed. With a direct or medial hernia, both men and women should be treated alike on these principles. The operation should thus conform to the varying conditions presented by individual cases.

Substances Resembling Epinephrin in the Blood Serum.—Rassers made extracts of serum from cattle, sheep, rabbits and guinea-pigs and tested their vasoconstricting action on the surviving intestines of white mice, arteries taken directly from just slaughtered cattle, the uterus of cats, etc. Both crystalloid and colloid elements of the serum seemed to be involved in its vasoconstricting action, and in increasing the tonus of the mouse intestine and rabbit uterus, while they reduced the tonus of the uterus cornu of the nongravid cat.

Acta Medica Scandinavica, Stockholm

March 6, 1920, 53, No. 1

- *Experimental Chronic Pancreatic Diabetes after Partial Pancreatectomy. E. Langfeldt.—p. 1.

Experimental Diabetes After Partial Pancreatectomy.—This entire number of the Acta is devoted to the account of two years of research on the development of glycosuria in dogs of different ages after partial resection of the pancreas. The metabolism was rendered more like that of human beings by feeding the dogs with carbohydrates and no meat. The methods of resection of the pancreas were also varied in different animals, to ascertain whether the removal of different parts of the pancreas has any special significance. Twelve photomicrographs are given of the necropsy findings, and a bibliography of 167 titles is appended. The findings all confirm the preponderant rôle of the pancreas in the origin of all diabetic phenomena. It seems to have a catalytic action. When the sugar content in the blood was more than 0.19 per cent., glycosuria followed, and the duration of the high sugar content was of greater import than higher concentrations for shorter periods. Glycosuria, albuminuria and cataract developed in the dogs analogously to what is observed in human diabetics. The ketonuria was also like that in man, but none of the dogs died in coma. The 192 page article is in English.

- *Meningococcus Infection Simulating Uremia. A. Wallgren.—p. 193.
*Corynebacteria and Allied Bacteria. H. Bergstrand.—p. 209.

Meningitis with Acute Nephritis.—Wallgren reports a case in which the first symptoms from meningococcus infection were sudden hemorrhagic nephritis in the previously healthy young man. Not until several days later did the typical meningitis symptoms appear. The kidney symptoms, fever and headache were ascribed to uremia until, the fifth day, stiffness of the neck led to lumbar puncture and discovery of the meningococcus. In a second case the young man had had acute nephritis five years before and the weakness, headache, vomiting and somnolency and high blood pressure were ascribed to uremia. The Kernig sign the third week led to lumbar puncture and the meningococcus was found. After a phase of progressive improvement, death occurred from a focus of softening found in the brain. There was undoubtedly associated uremia, testified by the renal insufficiency, subsultus tendinum noticed, on one occasion, and the necropsy findings. In a third case a boy of 5 presented the same train of symptoms, first the nephritis and a few days or weeks later the meningitis. In Rist's case, purpura was the first manifestation of the meningococcus infection, and the fatal meningitis did not develop until ten weeks later. In the entire group, the clinical picture at first was that of uremia from the unmistakable nephritis, and there was nothing to suggest the imperative necessity for antiserum treatment. The article is in French.

Corynebacterium Found in Case of Leukemia.—Bergstrand found a micro-organism of the corynebacterium group in pure cultures in the lymph glands excised from the elbow and groin of a man of 49 with lymphoid leukemia. In connection with these findings he discusses bacteria in general, emphasizing that bacteria have more changeable forms than has been hitherto realized, and relating his reasons for assuming that bacteria are nearer to the fungi than is usually accepted. The article is in German, and is illustrated.

THE CHANGE OF TYPE OF DISEASE *

SIR HUMPHRY ROLLESTON,

K.C.B., M.D., F.R.C.P.

Emeritus Physician, St. George's Hospital; President, Royal
Society of Medicine

LONDON, ENGLAND

Alteration of type of acute disease—a problem which exercised our professional ancestors, notably Sydenham—has recently come under discussion especially in connection with epidemics prevalent during the war, and may therefore serve as the subject for a few remarks. Although the debate rages mainly between the epidemiologists and the bacteriologists, the outcome is of great interest to the clinician.

Sydenham, whose position as an epidemiologist has been defined by Major Greenwood,¹ pointed out that acute diseases showed (1) a long period evolution with a rise, decline and fall, extending over centuries, and (2) seasonal variations with waves measured in months so that their character and their reaction to treatment varied at short intervals, a method successful in one epidemic becoming dangerous in a subsequent outbreak. Though, as Crookshank² points out, Ballonius (1574) anticipated him, Sydenham also (3) postulated the theory of epidemic constitutions to the effect that a special influence—telluric or climatic—becomes dominant and impresses some peculiar features on the clinical manifestations of diseases prevalent at the time to the exclusion of other types or symptoms, the amplitude of this wave being measured in years. Greenwood translates the much discussed term epidemic constitution as meaning that the non-specific secondary infections, such as those so plentifully exemplified in measles and influenza, are as important from the point of view of morbidity and mortality as the specific causes of the disease. Sydenham, of course, had no knowledge of the *verae causae* of disease or bacteriology, but with this knowledge Hamer, following the lines of the English Hippocrates, eloquently argues that members of the "catarrhal group of diseases," namely, cerebrospinal fever, acute poliomyelitis, encephalitis lethargica and influenza, are variants of the same morbid process, i. e., diverse manifestations of the same virus, under special conditions; this represents the most extreme divergence of the epidemiologic from the bacteriologic points of view.

That the type of disease changes has been disputed and it has been asserted that the supposed change is in

the mental outlook of the observers. Markham,³ in 1864, vigorously attacked the theory that there was a change in type of disease, and controverted the view that about 1832, after the epidemic of cholera, the type of fever previously sthenic became asthenic so that bleeding was no longer well borne. He in fact suggested that the notion of a change of type of disease was largely invented, years after 1832, to explain the abandonment of bleeding in inflammations and fevers.

At the present time no one doubts that certain diseases have shown changes of type; scarlet fever is universally recognized to have become much milder; Brownlee⁴ finds that though there is not any evidence that the amount of scarlet fever (or the infectivity of the causal agent) is less now than in the latter half of the last century, the mortality (or the virulence of the organism) has greatly fallen. Pneumonia is another example of a disease in which the virulence, as shown by the mortality, has increased, and the type of the disease has since the reappearance of influenza in 1889-1890 undergone some change, the disseminated form being common and the frank lobar pneumonia less frequent. The seasonal variation of type was shown in a well-marked degree by the two waves of influenza in the spring and autumn of 1918, the high rate of thoracic complications and of mortality in the second wave being associated with *Streptococcus hemolyticus* and the pneumococcus.

In the Royal Navy the spring wave of influenza was accompanied by 0.4 per cent. of complications and 0.03 per cent. mortality, whereas in the autumn wave the incidence of complications was 6.8 per cent. and of deaths 2.8 per cent.⁵

It would, indeed, be remarkable if diseases always respected the types conveniently accorded them in textbooks, for, as Sir Clifford Allbutt long ago insisted, a disease is not a fixed entity but a reaction of the body to some infection or irritant.

Alterations in the clinical features of diseases usually regarded as typical may be due to several causes. It is obvious that variations may occur, on the one hand, in the causes as regards their virulence and, on the other hand, in the resistance of the patient. A change in the clinical manifestations may therefore be explained on bacteriologic grounds, by the supposition of changes in the soil, or of changes in both these factors. The permutations and combinations thus possible would explain many changes in the character of disease; thus, a highly virulent state of the infective agent acting on a susceptible individual with greatly lowered resistance would tend to produce a fulminating attack, whereas an attenuated virus acting

5. Hill, R.: J. Roy. Sanit. Inst. 40, 1919.

on an individual with good resistance might fail to produce any effect or cause an abortive illness, thus conferring immunity.

The difficult question arises whether or not bacteriology and changes in the resistance of the race, either comparatively permanent as the result of environment or transient from disease or other factors, will together satisfactorily explain alterations in the clinical type of disease; or whether there is some further and mysterious factor, such as is implied by some epidemiologists, which has yet to be thoroughly elucidated. Though I shrink from expressing a dogmatic opinion, the first explanation seems the more attractive.

BACTERIOLOGIC REASONS FOR CHANGE IN TYPE OF DISEASE

Bacteria may vary in their pathogenicity either as the result of external influences or spontaneously when no such factor is obvious. External conditions, such as temperature and other climatic factors, concentration of their carriers and hosts, and conditions of passage, may influence the vitality and virulence of micro-organisms. It has also been suggested that micro-organisms have cycles of infective activity following periods of rest, and that this cycle explains by its periods of high infectivity the occurrence of epidemics; the influenza virus appears to have a cycle of thirty-three weeks, and the various strains of the infective agent of measles cycles of eighty-seven, ninety-eight and 110 weeks.⁶ It would naturally follow, though proof is required, that further variations in the virulence of the germ might alter the character of the clinical manifestations. Then again, the same specific organism may give rise to clinical features of varying character; thus, the influenza bacillus may be associated with symptoms of coryza, meningitis, rheumatic fever, or of typhoid fever; and this variation may be seen in the same epidemic, as in the epidemic in Hertfordshire of protean symptoms due to *M. catarrhalis* reported by Merwyn Gordon and Dunn. These variations may, it is true, be eventually explained in some other manner, namely, by the existence of some additional factor, such as an ultramicroscopic organism or by ultramicroscopic bodies of the nature of enzymes (enzyme theory of disease) associated with the bacteria.⁷

Another bacteriologic explanation for change in the clinical type of disease is naturally attractive. In a disease such as enteric fever, variations in different outbreaks may be due to different strains of the infecting organism; this has been shown by the division of enteric into (a) typhoid due to *B. typhosus* and (b) paratyphoid A and (c) paratyphoid B, both with a lower mortality; and so what might have been regarded as a change of type is really explained by the occurrence of different though allied infections. In cerebrospinal fever the different types of meningococci may be correlated with different clinical types; thus Dopter⁸ showed that the predominant infective meningococcus before the European war was Type A (Gordon's Types I and III), and that later it became Type B (Gordon's Types II and IV); and Netter⁹ correlated the greater frequency of septicemic cases and lesions such as rashes, arthritis and iridocyclitis

with this change to Type B. The differentiation of the types of pneumococci is another example of the influence of different strains or types of an organism in determining different clinical types of a disease previously regarded as due to one organism. The different clinical types of bacillary dysentery due to *B. dysenteriae* Shiga and *B. dysenteriae* Flexner have been well established during the war. This explanation of different clinical types as depending on different strains or types of the infecting organism is so logical that it is tempting to adopt it widely, and perhaps especially for diseases in which the nature of the infecting organism has not yet been established.

The occurrence of secondary infections, such as the pneumococcus and *Streptococcus hemolyticus* in measles and influenza, is a powerful factor in the change of type of disease, and has already been mentioned as an explanation of Sydenham's epidemic constitutions. It may be surmised that the liability to secondary infections may depend either on a previous want of resistance in the patient or on such a virulent primary infection that the patient's resistance is at once broken down.

The influence of prophylactic inoculation in preventing the incidence and modifying the course of smallpox, typhoid and pneumonia (F. S. Lister) are too well known to require elaboration. But attention may be directed to the suggestive work of Vaughan¹⁰ and his collaborators on the question of a nonspecific immunity conveyed by common infections, especially those of the respiratory system, against others by which the severity of the subsequent disease among those, especially town inhabitants, is diminished by a previous infection.

CHANGE IN THE RESISTANCE OF THE PATIENTS

Long ago a change of type of disease—an alteration from the "sthenic" to the "asthenic" form of fevers—was thought to have occurred as the result of the cholera and influenza epidemics of 1832 and 1833 (Watson). And the altered conditions of life entailed by the concentration in cities of persons previously living in country districts has been brought forward to the same effect, though this is rather contrary to Vaughan's contention mentioned above. In our own time influenza has exerted an influence in the form of pneumonia, at any rate to the extent of making the disseminated or bronchopneumonic type commoner.

The varying resistance of the population to disease is concerned with both the periodicity of disease and the character of the epidemics. The epidemics of measles in Great Britain occurring at intervals of from eighty-seven to 110 weeks (Brownlee) are commonly assumed to depend on the accumulation of susceptible children in sufficient numbers, though, as is pointed out above, another factor may be considered. In isolated districts where measles rarely occurs, the introduction of the infection causes a widespread and severe epidemic, as in the classical instances of the Faroe Islands (1781 and 1846), Fiji (1875 and 1907), in the neighboring island of Rotuma in 1911,¹¹ and in the Shetlands. These examples suggest that the absence of immunity is responsible. On the other hand, the gradual diminution in the severity of at least the outward manifestations of syphilis might be thought to depend to some degree on a general

approach to relative immunity; but here the question of treatment comes in, as it does in regard to diphtheria, which has also been thought to have independently become less virulent.¹²

The resistance of individuals and races is obviously influenced by environment, such as overcrowding, overwork, bad food and alcoholism, and thus both the incidence and the severity of the disease—conditions which must be distinguished from each other—become increased. Among the Italian armies during the war a tendency to get manifestations of scurvy in various infections was noted. In his recent Lumslean lectures at the Royal College of Physicians of London, Sir John Rose Bradford expressed his opinion that war nephritis, which has been regarded as a special form, was only acute nephritis occurring on a large scale in young and previously healthy men. It may, however, be difficult to differentiate between the effect of improved hygienic conditions, on the one hand, and of diminution in the virulence of the infecting organism, on the other; thus, the disappearance of typhus from Glasgow and other towns was naturally ascribed to improvement in the living conditions; but Brownlee points out that this disease simultaneously subsided in the West Highlands and Ireland, where no such sanitary alterations occurred, and argues that the virulence of the infecting organism became attenuated.

EXPERIMENTAL STUDY OF THE NASOPHARYNGEAL SECRETIONS FROM INFLUENZA PATIENTS

PRELIMINARY REPORT *

PETER K. OLITSKY, M.D.

AND

FREDERICK L. GATES, M.D.

NEW YORK

This experimental study of the nasopharyngeal secretions from influenza patients was made during the course of one and a half years in three successive periods. The first period coincided with the epidemic wave of 1918-1919. During this period were studied actual cases of acute uncomplicated influenza and persons who had never been affected. The second period embraced the late autumn of 1919, during which influenza did not prevail in New York in epidemic form. During this interepidemic stage, healthy controls were studied. The third period, during the winter of 1920, saw a return of the epidemic. At this time additional cases of the disease were available for investigation.

By proceeding in this manner we hoped to check our results for each period against one another. As the sequel will show, we believe we succeeded in this undertaking, with the consequence that we are enabled to present our findings with perhaps a degree of confidence not otherwise appropriate.

In planning our experiments we had in mind the possible presence, in the nasopharynx of persons suffering from acute epidemic influenza, of some agent the effects of which might be noted in animals.

In considering the criteria of activity of this agent, we thought in the first place of the well known phenomenon in man of leukocytic depression, involving

especially the mononuclear cells, during the acute influenzal infection. In the next place, we had in mind changes of a more or less pronounced but possibly transient character, arising in the lungs, which might conceivably predispose to the severe pneumonias that often accompany as a secondary or concurrent infection the influenzal attack.

The materials with which we worked were the saline washings from the nose and throat. We secured these materials from eight cases of influenza within the first thirty-six hours of the disease, and from twelve cases at later stages, namely, either during convalescence or the period of the postinfluenzal pneumonia. In addition, fourteen persons, during the epidemic or interepidemic periods, believed never to have had influenza were washed in the same manner and their washings studied.

Full grown rabbits were used for inoculation, and no rabbit suffering from snuffles or any detectable disease was employed. All animals were subjected to preliminary blood counting, temperature taking and weighing, and any showing variations beyond the average were discarded. These observations were made on three to seven successive days previous to inoculation.

The inoculations were made directly into the lungs by means of the intratracheal catheter; 3 c.c. of material was the usual dose for a 2.5 to 3 kilogram rabbit, and consisted of (a) the unfiltered nasopharyngeal washings, (b) the filtered washings, (c) lung tissue suspensions, filtered and unfiltered, from previously inoculated rabbits, and (d) similar lung tissue preserved in sterile 50 per cent. glycerin.

It is desirable, in this place, to state that unfiltered washings were employed in the expectation that they could be purified, or rather deprived of their ordinary bacteria, by successive animal passages. It was believed that if this could be accomplished there might be a better chance of preserving and, possibly, bringing to multiplication some other variety of microorganism, more resistant and virulent perhaps, which would give to the washings from cases of uncomplicated influenza a quality lacking in others. It was, of course, realized that not in every instance could this favorable outcome be looked for. Now and again it was to be expected that a virulent pneumococcus or streptococcus would set up a pneumonia to which the animal would succumb. But if the ordinary bacteria could be suppressed by animal passages in a few instances and something survive which produced definite changes in the structures of the rabbits—in the blood and lungs, for example—the washings from cases of influenza might thus be characterized in a way distinguishing them in effects from the washings of another origin. In this manner the operation of a usual pathogenic agent is to be deduced, although it might not be possible to determine certainly that this agent is the inciting microbic agent of influenza. However, if a certain correspondence in tissue and other effects can be shown to exist between the person suffering from influenza and the rabbit inoculated with materials originally derived from influenza cases and free from all ordinary bacteria, a probability as to the nature of the pathogenic agent is introduced into the calculation which encourages further investigation along the indicated lines.

There were inoculated into the lungs of rabbits the unfiltered nasopharyngeal secretions from five cases

* From the Laboratories of the Rockefeller Institute for Medical Research.

during the first epidemic and three during the second, in the first thirty-six hours of the disease; and from eleven cases during the first epidemic and one during the second in the later stages of the affection.

RESULTS OF EXPERIMENTS

The following effects were induced by the materials from seven of the eight fresh cases, but not by any of those from the twelve cases examined after thirty-six hours.

Clinical Effects.—From twenty-four to forty-eight hours after inoculation, fever developed, associated with the ordinary signs of indisposition in a rabbit, such as listlessness and ruffled hair. This was accompanied by conjunctivitis, varying from injection to pronounced catarrhal inflammation. The striking feature, however, was the definite and often marked leukopenia resulting from the depression of the mononuclear cells, as shown in the accompanying chart. If the condition was allowed to run its natural course, these symptoms endured for three days, the animal then returning to normal. If the rabbit was killed—for if the condition remained uncomplicated by ordinary bacterial infection none died—a n unusual pathologic picture was revealed.

Pathologic Effects.—The respiratory organs were affected to the exclusion of all other structures. No pleuritis or exudate in the pleural cavity was evident. The lungs were voluminous and edematous, and had a mottled, hemorrhagic appearance. The hemorrhages on the surface, beneath the pleura, were diffuse or discrete, occupying areas of a few millimeters in extent, or covering a large part of a lobe. In addition, minute petechiae occurred. On section of lungs the cut surface revealed a hemorrhagic edema; it dripped a blood-stained, frothy fluid. The hemorrhages again were either diffuse and large or discrete and small; in the latter instance they were numerous.

Microscopic sections of the lungs were made through various parts, the base, periphery or hilum, and as a rule were carried through the hemorrhagic foci. The hemorrhages were either diffuse, invading large areas of pulmonary structure, or were localized to small areas, or seen as extravasations into the interalveolar and intra-alveolar structures. The edema was pronounced: the alveoli were filled with serum, and there was a serous exudation in the interalveolar strands. The lung structure showed a cellular exudate, comprising polymorphonuclear cells showing usually large eosinophilic granules; large cells of an alveolar type,

probably desquamated bronchial epithelium, and in the interalveolar strands, mononuclear cells. Some fibrin was present as well. The bronchi were partly filled with erythrocytes, fragments of degenerated and exfoliated epithelia, and leukocytes. Their walls here and there had lost their epithelial lining, and were hyperemic and thickened. The capillaries were distended with blood.

No ordinary bacteria were seen in impression films of the lung tissue or in sections stained by Gram's or MacCallum's method, or in cultures of the tissue.

If the clinical effects observed continued for forty-eight hours, the animal as a rule was killed, and the affected lung tissue was ground, suspended in saline solution, and injected into the lungs of a new series of rabbits. In this way the clinical and pathologic effects were passed through as many as fifteen successive rabbits.

These effects were obtained only with the nasopharyngeal secretion in seven of eight patients, collected within thirty-six hours after the onset of the first symptoms. Twelve cases of influenza, in which the washings were collected forty-eight hours after onset and in the stage of convalescence or of secondary pneumonia, failed to give the same results.

Control experiments were made by injecting into the lungs of rabbits saline solution, suspensions of normal rabbit lungs, normal rabbit serum, foreign protein, such as human ascitic fluid, bacteria of the ordinary species, including Pfeiffer's bacillus and its poison as prepared by Parker's method, and finally the nasopharyngeal

Chart illustrating effect on blood count. To be noted are the rise in temperature and the depression in the total white blood cell count caused by a deficiency of mononuclears. 1, first rabbit passage of the nasopharyngeal washings from a fresh case of uncomplicated influenza; also the normal curve of this animal prior to injection; 2, second rabbit passage; 3, seventh rabbit passage.

secretions from fourteen persons free from influenza and tested in the epidemic and interepidemic periods. Of the latter, seven suffered from early or later stages of coryza. None of the animals inoculated with the control materials or these secretions showed the same clinical and pathologic action; a few gave a polynucleosis with frank lobar pneumonia; others, a mononucleosis without visible lung involvement, and still others, inconstant effects.

A closer study was then made of the agent causing these phenomena, and it was found that although it was extremely difficult to secure these results with filtrates obtained directly from the patient's secretions, they could be obtained by first passing the material through a series of rabbits. Then repeated filtration through Berkefeld "V" and "N" candles between rabbit passages did not hinder the development of the typical clinical and pathologic effects,

We determined that the agent was able to resist the action of sterile 50 per cent. glycerin for nine months, but probably not for a much longer period. In one series of experiments glycerinated material free from ordinary bacteria was passed with typical effects through ten successive rabbits.

No case of the uncomplicated effect in the rabbits terminated fatally. By "uncomplicated" we mean that cultures of lung tissue after the sacrifice and of blood during the illness yielded no growth of ordinary bacteria.

But although these effects were produced repeatedly in rabbits with material free from ordinary aerobic bacteria, the latter micro-organisms were encountered occasionally in the course of the experiments.

Those animals in which the inoculation terminated fatally did yield growths of various bacteria from the lung tissue, thus: pneumococcus, Group IV, eleven times; atypical II, three times; *M. catarrhalis*, a gram-negative hemoglobinophilic organism resembling Pfeiffer's bacillus, and *B. pyocyaneus*, each twice; *Streptococcus viridans*, streptothrix, and *B. coli-communis*, each once. Generally the same organism was not found regularly in the consecutive rabbit passages of a series of transmissions. For example, in the filtrate series of Case 17 the fifth passage showed a pneumococcus Group IV, the seventh and eighth *B. pyocyaneus*, and the tenth a gram-negative, hemoglobinophilic micro-organism, resembling Pfeiffer's bacillus. The other passages were free from such bacteria. In three of the seven series of transmissions, the ordinary bacteria in the secretions were suppressed completely, and all the animal passages remained free from them.

The pathologic picture when complicated by these ordinary bacteria showed severe, extensive lobar or bronchopneumonia with fibrinous and exudative pleurites and abscess formation and, as a rule, a rapid decline and death of the animal.

A series of investigations was undertaken in which an effort was made to reproduce the last mentioned conditions experimentally. Rabbits were injected with the influenzal material intratracheally and later with small nonpathogenic doses of the pneumococcus, Pfeiffer's bacillus, and *Streptococcus viridans* intravenously. In these animals the bacteria localized themselves in the lungs, producing extensive lobar pneumonias or bronchopneumonias with pleurites and, as a rule, leading to death. Hence apparently this material obtained from the nasopharyngeal secretions in early influenza diminishes the resistance of the rabbit's pulmonary structures against invasion by these common micro-organisms.

CONCLUSIONS

From the evidence obtained in this study, extending over one and a half years, it would appear that there occurs a specific substance in the nasopharyngeal secretions in cases of epidemic uncomplicated influenza. This substance seems to be present only in the early hours of the disease. It has not been found later than thirty-six hours after the onset, nor in cases of secondary pneumonia, nor in secretions from persons free from the syndrome of influenza either during the epidemic or during nonepidemic periods.

With this substance we have induced a clinical and pathologic condition in rabbits, affecting the blood and pulmonary structures mainly, which could be maintained and carried through at least fifteen successive animals. For this reason, and also because of the

dilution between passages and the shortening of the incubation period from rabbit to rabbit, we are led to believe that we are dealing with the actual transmission of a multiplying agent rather than with a passive transference of any original active substance.

This active substance is filtrable, and resists the action of sterile 50 per cent. glycerin for nine months, but probably not for a much longer period.

The manner in which the bacteria of ordinary species, such as the pneumococcus, the Pfeiffer bacillus, *Streptococcus viridans* and others are encountered during the course of the transmission experiments and during the experimental reproduction of the condition described justifies the opinion that these micro-organisms are secondary in effect. The essential effects are produced by a substance wholly unrelated to these bacteria.

The similarity that exists between these effects in rabbits and those occurring in man lays a basis for further investigation on the inciting agent of influenza.

It may be stated here that during the course of these experiments we have seen in cultures, both from the lung tissue of affected rabbits and in the filtered nasopharyngeal washings from cases of influenza, tiny bodies, almost invisible, which decolorize by Gram's method, and which stain generally with difficulty with nuclear dyes. This phase of the subject is still under investigation.

THE BACTERIOLOGY OF THE URINE IN RENAL TUBERCULOSIS *

J. DELLINGER BARNEY, M.D.

AND

EDWARD S. WELLES, M.D.

BOSTON

It has long been generally believed that the urine in tuberculosis of the urinary tract is sterile. On this basis one feels fairly safe in assigning to tuberculosis those cases in which there is a cystitis with pyuria and a negative culture. But in view of our experience in the Genito-Urinary Department at the Massachusetts General Hospital, it has seemed worth while to look into the question with some care.

According to Rafin,¹ it was Melchior who, in 1895, asserted that the urine in urinary tuberculosis² was aseptic, a statement which was confirmed by Nogués³ in 1899. Meanwhile, in 1897, Albarran³ maintained that tuberculous urine was almost always secondarily infected.

This apparent discrepancy of opinion on the part of competent observers may be explained by the work of subsequent investigators. Sutter,⁴ in 1907, studied seventy-eight cases of urinary tuberculosis and obtained positive cultures in nine, of which seven patients had been previously catheterized or otherwise subjected to instrumentation. In the same year Wildbolz⁵ found secondary infection in 22 per cent. of his cases, but regarded it as due to previous local treatment. In 1911, Pousson¹ reported twelve secondary infections

in thirty-two cases. This work was followed in 1912 by that of Rafin,¹ who made 239 bacteriologic examinations of the urine in urinary tuberculosis. The female patients were catheterized, but in the male the urine was voided into a sterile flask after local antiseptics and the passage of the first portion of the urine. Positive cultures were obtained in seventy-one or 29.6 per cent., the staphylococcus being found fifty-eight times, the colon bacillus three times, and streptococci twice. Rafin ascribed his positive findings, as did his predecessors, to the fact that previous instrumentation, improperly carried out, had been performed. None the less it seems clear that the evidence thus far obtained strongly favors the view that tuberculous urine is generally sterile.

In 1918, Spooner⁶ made a very careful bacteriologic study of ten tuberculous kidneys freshly removed at operation. While he could demonstrate the tubercle bacillus by one means or another in all, he found evidence of secondary infection in none. Cultures from seven urines of patients suffering from renal tuberculosis were examined. In three instances, catheter specimens of the bladder urine showed organisms other than the tubercle bacillus. In four cases the urine obtained from the ureter on the infected side showed no growth on ordinary culture mediums after forty-eight hours' incubation. Spooner concludes that whereas the urine from a tuberculous kidney, if obtained from the ureter, shows no evidence of mixed infection, the bladder urine is often contaminated by other organisms.

Recent advances in cystoscopic and bacteriologic technique now enable us to study this interesting and important question with more accuracy than has heretofore been possible. Whereas formerly the specimens were generally obtained only from the bladder, often without a catheter, they are now obtained not only from the bladder and by catheter, but from the separate kidneys as well. Furthermore, we have come to place little or no reliance on the culture of a specimen of urine, having found that contaminating organisms from one source or another may and often do vitiate the results. Instead, dependence is now placed largely, if not entirely, on smears of the centrifugalized sediment of the fresh urine, a technic for the perfection of which we must thank our colleague Dr. E. G. Crabtree. By this means we are able to demonstrate not only the tubercle bacillus in the great majority of cases, but also the presence of secondary organisms.

RESULTS OF OBSERVATIONS IN SIXTY-THREE CASES

It has therefore seemed worth while to examine the records of hospital and private cases which have been so studied. We have accordingly collected sixty-three instances, with more or less complete data. In all, the diagnosis has been proved either by finding the tubercle bacillus in the urine, by operation, or at necropsy. The urine from the tuberculous kidney has been centrifugalized, and the sediment stained and examined in all cases from which it could be obtained, that of the healthy side in the great majority. A smear of the bladder urine has been examined in many, chiefly in those cases in which the tuberculous ureter could not be catheterized. In many of these cases, previous instrumentation of one sort or another, performed not always *secundum artem*, had been car-

ried out. It is impossible to say whether or not this has influenced the results, but we firmly believe that while it may have vitiated certain bladder findings, it has had little or no effect on the kidney urines.

Cultures from the bladder were made in thirty cases with fifteen positive results, in ten of which the symptoms dated anywhere from one to ten years. This would suggest either that the antiquity of the disease was a factor, or that during these years secondary infection had been invited by means of the promiscuous and futile local treatment to which many of these patients had been subjected.

Cultures of the right kidney urine were made thirty-one times with seven positive results, and twenty-eight times from the left kidney with six positive results. In these, as in the bladder urines, the colon bacillus was most commonly found. The data as to the duration of symptoms in these particular instances are of no special value. It will be observed, however, that whereas in the bladder urine the cultures were positive in 50 per cent., in the kidney urines positive results were obtained in but 22 per cent., indicating a greater ability of the kidney to remain aseptic than the bladder. This statement is somewhat emasculated by the fact that of the thirteen positive cultures from the kidney, eight were on the healthy side and only five on the tuberculous side. We have previously stated, however, that comparatively little reliance can be placed on the results of cultures, and these data are given only for what they are worth.

Smears of the bladder urine showed secondary infections in twenty-one cases, and as in the cases from which cultures were made, there were more with a duration of years than of months.

Smears from the kidney urines were made in all cases in which it was possible to catheterize the ureter. Secondary organisms were found in only five instances, three times on the right, of which two were on the healthy side; twice on the left, of which one was from the sound kidney.

Combining the results of cultures and smears from the separate kidney urines, it is found that positive results were obtained on the healthy side in eleven cases, and on the tuberculous side in seven; a total of 28.5 per cent. of secondary infection of the kidney urine in sixty-three cases.

While we have found no adequate explanation for the popular belief that tuberculous urine is sterile, it has been suggested, but never demonstrated so far as we know, that this comparative asepsis is due to the excessive acidity of such urine. In our cases the reaction of the bladder urine to litmus was tested in all at least once, often many times. In twenty-eight of the sixty-three the reaction was alkaline either once, several times or on all occasions (twelve cases). In some of these urines, decomposition had doubtless occurred, owing to a too prolonged residence in the laboratory; in others, an accurate chemical test may well have shown that the alkalinity to litmus was in reality chemical acidity. A few observations made by us on fresh tuberculous urine obtained by ureteral catheter have shown a maximum hydrogen ion concentration of 5.3 while some tests made by Henderson and Palmer⁷ showed a concentration of only 6.7, and even 7.4. This is a far lower acidity than was found by these observers in a number of other patho-

6. Spooner, L. H.: J. M. Research 39: 59 (Sept.) 1918.

7. Henderson, L. J., and Palmer, W. W.: J. Biol. Chem. 13: 393, 1912-1913.

logic conditions. On the other hand, Labbé and Vitry,⁸ in 1914, after an elaborate investigation of the comparative total acidity of the urine in tuberculosis and in other conditions, found that this acidity was greatest in the tuberculous cases. It would appear, therefore, that while tuberculous urine is generally acid, it seems never to be excessively so, and may at times be neutral or even alkaline.

That the reaction of tuberculous urine in and of itself is not hostile to the growth of the colon bacillus is shown by our own clinical data (in one kidney large numbers of tubercle and colon bacilli were found in the same smear). We have also found that, after examination, specimens of tuberculous urine which have been left standing in the laboratory often show a profuse growth of organisms from accidental contamination. Furthermore, Shohl and Janney⁹ have demonstrated experimentally that the colon bacillus will grow in urine with a fairly wide range of hydrogen ion concentration, the optimum for growth being from 6.0 to 7.0. On the other hand, bacillary growth is inhibited in urine with acidity of from 4.6 to 5.0. As the latter figure shows an acidity but slightly greater than that which we have ourselves obtained, it would suggest that in some instances at least the acidity of the urine is such that while secondary organisms may not be actually killed, their growth is at least inhibited. The few observations that we have made have shown the desirability of further study, and this we hope to take up at some future time. It has been suggested that some endotoxin secreted by the tubercle bacillus may be a factor in the production of asepsis. This may eventually prove to be the case; but we find that the knowledge of such an endotoxin is still meager, and no statement at all has been made as to its possible bactericidal properties.

There is no question that infection of one kidney exerts an inhibitory and depressive influence on its uninfected mate. Albarran long ago made this observation, and it has since been confirmed by many others. Today our more precise methods of measuring kidney output enable us to gage this toxemia before the excision of the diseased kidney, and to demonstrate its elimination after operation. Possibly this depressive effect on the healthy kidney accounts for the fact that its urine is found to contain secondary organisms more often than does that of the tuberculous kidney. This theory by no means, however, furnishes a satisfactory answer, for it does not tell us why the tuberculous kidney, whose resistance was so low at the outset that the tubercle bacillus obtained a foothold and which has been still further depleted by its ravages, should not more often play host to other organisms.

Those who hold to the view that bacteria can pass from bladder to kidney by way of the ureteral lymphatics may offer this as a possible explanation. The blocking of these lymphatics by the early and extensive involvement of the ureter in renal tuberculosis would certainly help in keeping such an organ sterile; and by the same token the unimpaired lymphatics of the healthy kidney would offer an explanation for the more frequent infection of this organ. We believe, however, that organisms reach the kidney through the blood stream in the majority of instances.

CONCLUSIONS

1. Cultures of urine are unreliable. Far greater dependence is to be placed on a properly prepared smear of a fresh sediment.

2. Cultures and smears have shown positive results from the bladder urine in 55.3 per cent., and from the kidney urine in 28.6 per cent. The sound kidney has yielded positive findings more often than has its tuberculous mate.

3. Tuberculous bladder urine is generally acid, but may be neutral or alkaline. The kidney urines, so far as studied, have been strongly acid.

4. In general, it may be said that there is as yet no adequate explanation for the comparative asepsis of tuberculous urine. Its usually high acidity is probably an important factor. The greater number of contaminations in the urine from the sound kidney may be due to the toxemia produced by its tuberculous mate; but we can give no reason for the sterility of the latter organ.

5. Our results show conclusively that while a negative smear or culture from the bladder in a case of cystitis and pyuria points strongly to tuberculosis, a positive smear or culture from the bladder, or even from the kidney urine, does not exclude this disease.

TESTICLE TRANSPLANTATION

L. L. STANLEY, M.D.

AND

G. DAVID KELKER, M.D.

Resident Physician and Assistant Resident Physician, Respectively,
California State Prison

SAN QUENTIN, CALIF.

The term "interstitial gland" was first brought to our attention by articles in the press referring to Serge Voronoff of Paris, who was said to have transplanted these organs from apes to man, with brilliant results.

"Interstitial" cell was the term used in an editorial¹ in *THE JOURNAL*, in which the work of Steinach on the development of secondary sexual characters was discussed. The editorial concluded that:

The sum total of the foregoing observations tends to confirm the view, expressed by several authors,² that the essential factors for the production of the genital hormones are the "interstitial" cells found in both the testes and ovaries of various animals. The genital glands are thus believed to contain gland cells of two distinct and functionally independent types. These interstitial cells, however, are apparently not universally present. It has been shown that, by means of the roentgen rays, it is possible to destroy the germ cells in either testes or ovaries, so rendering the animals sterile. Whether the interstitial cells, which are not destroyed by these rays, are originators of the unique effects in respect to secondary sexual development and the awakening of mammary activities remains to be determined.

The various reports of Lydston first attracted our attention to the procedure of implanting testes from the dead body to the living. As there are on the average three executions in this prison each year, valuable material for this kind of work became available.

Our first implant was done in August, 1918. Altogether, operations have been performed in eleven cases

with human material, and five with testicles removed from young rams. The time elapsing since the use of the animal tissue has been too short to make any deduction as to its value.

In five patients, only one testicle was implanted into the scrotum, while in six others, double transplantation was performed. Results have been apparently as good with the single as with the double graft. One whole testicle of a ram was embedded in the scrotum of each of two patients, but they began to slough in seven and sixteen days, respectively. One came away entirely, while a small part of the other remains after six weeks. In three other cases, only half of a ram's testicle was used, but in all, sloughing began seven days after the operation.

With the human material the implant, denuded of the parietal tunica vaginalis, was in three cases placed in a bed made in the scrotal tissues; in seven, testicles were grafted on the atrophied gland of the recipient; and in one double implantation, one testicle was embedded in the right scrotum, and a denuded surface of the other sewed on a similar section of the gland on the left. It is believed that the engrafting gives better results than the embedding.

These operations were performed for the most part with local procain anesthesia, although spinal anesthesia also was used.

REPORT OF CASES

CASE 1.—The first patient operated on, aged 25, rather dull mentally and inactive physically, had had both testicles injured by a kick five years before. A double transplantation from a negro, aged 27, apparently had a beneficial effect on him, in that he became more active, talked more, wrote better letters, comprehended jokes, and had more sexual activity than before. After leaving the prison he was employed in a lumber camp, where the superintendent stated that he was considered better than the average laborer, and that he was quite industrious and performed the required work very satisfactorily. This contrasts markedly with his condition before operation.

CASE 2.—A man, aged 50, had atrophied testicles as the result of orchitis following mumps. His sexual ability was greatly impaired, leading to domestic unhappiness and divorce. One testicle taken from a Mexican, aged 27, was implanted in him in February, 1919. Five days afterward he had an erection and continued to have them nightly. He said that his general health and outlook on life were better than they had been for years. Three months after the operation the implant was reduced slightly in size. Six months afterward it became the size of a cherry, and the patient reported that sexual desire was somewhat decreased as compared to what it had been a few weeks after the operation. In November, eight and one-half months after the operation, the patient was induced to allow the implant to be removed. It was submitted to the Department of Pathology of the Medical School of Stanford University, where Dr. W. Ophuls rendered the following report: "Sections show that the testicle is entirely necrotic, the necrosis involving all epithelium and the connective tissues. In the periphery there has been a slight ingrowth of cellular connective tissue through the necrotic capsule. Considerable hematoidin in necrotic mass."

CASE 3.—H. K., aged 54, noticed declining sexual activity as well as mental languor, accompanied by testicular atrophy following a traumatic orchitis in 1916. June 20, 1919, a double testicle graft was performed, the material having been taken from a white man, aged 26. On the second and third day after the operation, there was only a tendency toward an erection, but on the fourth day there was a satisfactory one. Every night thereafter there was sexual manifestation, and four weeks afterward he had an ejaculation. No spermatozoa were found on microscopic examination. The man noticed an improvement in his eyesight. This improvement was verified by the visiting oculist of the prison, who examined his eyes several months after the operation, and compared his

findings with the patient's glass prescription of several years before. The oculist stated that there was an improvement of 50 per cent. The patient's whole attitude changed for the better. He showed more vitality and aggressiveness. He now moves more quickly, and is jubilant, whereas before he was slow and languid. Recently under erotic stimulation he has had strong erection and orgasm. A recent examination of the grafts reveals them somewhat reduced in size, and the juncture between the graft and the patient's testicle is plainly palpable. The patient has gained 45 pounds, feels fine, has continued sexual desire, and says that his strength is as good now as it was when he was 40 years old.

CASE 4.—B., aged 72, unmarried, had never had normal sexual impulses, sexual desire being almost unknown to him during his whole life. He came to prison for lewd and lascivious conduct with a minor child. His health had not been good for the last few years, and he was a frequent inmate of the prison hospital for various complaints attributable to his age. June 20, 1919, a double testicle graft was performed, the donor being an Indian boy, aged 19. The patient had an erection the third night after the operation, the first one that he had experienced for several years, according to his own statement often repeated. His general demeanor changed, and his improvement was noticeable to all with whom he came in contact. His voice became deeper, and stronger, and he often gave expression to the good state of his health. This changed condition has persisted, and now after ten months he continues to feel well and vigorous, and to have frequent erections. He has not been ill or in the hospital since the operation, although for six months preceding the graft our records show that he had been in the hospital for two or three days, with some complaint, every month.

In this case there has been some sloughing from both sides of the scrotum, and numerous long strings (tubules) were expressed. Much of the graft, however, was retained. These tubules showed degeneration.

The results of testicle transplantation in the other seven cases have been somewhat similar, except that in two of them little beneficial effect was noted. One of these two experienced some improvement, but nothing so marked as in the others. In the other patient there was a change of voice from a high tenor to a low tenor, reported to us by the choir leader.

COMMENT

It has been our custom to have our patients write reports of their condition each month, and these we have on file. At first it was thought that possibly the operation alone would have the psychologic effect of their writing favorable letters, and expressing themselves as greatly benefited. But we do not think that such, if it were the case, would persist after many months, as it has in these patients. A dissatisfied patient usually does not delay long in letting the operator know about it.

The results of the sheep testes transplantation, so far, are not encouraging, although one man, aged 65, seems to have been benefited. Much of the implant sloughed out.

Judging from our limited number of cases, the transplantation of human testicles has a decidedly beneficial effect on the well-being of the patient. We do not believe that the implant lives, as demonstrated in the second case cited above.

Probably during the process of necrosis, certain bodies are given off into the lymphatics or blood stream which stimulate the patient in some unknown way.

We are unable to determine whether these beneficial effects are due to any action of the interstitial cells of Leydig or any other definite part or parts of the

testicle, although we have certain evidence which seems to show that possibly the interstitial cells have more effect than the seminiferous structures. On microscopic examinations of the testicle to be implanted in Case 11 the epithelial cells of the seminiferous tubules were vacuolated and more or less degenerated. In places the intertubular tissue was dense and cellular. There were small islands of these cells scattered about, which might have been interstitial cells. They were relatively large, with rounded nuclei. The same tissue engrafted into a eunuchoid, aged 43, caused sexual desire to appear, whereas it had not been present before.

The length of time which these beneficial effects last has not been definitely determined by our work. It is probable that it lasts more than a year. All our patients that are benefited are still enjoying this improvement.

We do not make any claim that this procedure will increase longevity. This would be hard to establish, although we feel that any one that enjoys good health and vigor, and takes pleasure in living, will outlive a person with the opposite characteristics.

As sexual manifestations are a good indicator of one's state of health, we believe, judging from these as well as other indications, that beneficial effects may be produced by testicle transplantation.

BETANAPHTHOL POISONING IN THE TREATMENT OF HOOKWORM DISEASE *

WILSON G. SMILLIE, M.D.
SÃO PAULO, BRAZIL

In recent years it has been discovered that betanaphthol is useful in the treatment of hookworm disease. The dose of 0.2 to 0.5 gm., usually recommended for internal medication, has been regarded as only slightly toxic to the patient. Thymol and oil of chenopodium, the other two drugs commonly employed in the treatment of hookworm disease, have always been considered more effective than betanaphthol, but the dosage generally recommended produces toxic symptoms that are both more frequent and more severe than those caused by betanaphthol. Theoretically, betanaphthol should be a valuable addition to the anthelmintic armamentarium, if it can be proved efficacious and nontoxic.

Bayma and Alves¹ have established a new method for treating hookworm disease with betanaphthol, using larger doses than had before been employed. Their patients, treated in a hospital under careful supervision, received a preliminary saline purge and, on the next day, 6 gm. of betanaphthol in divided doses: 1 gm. every fifteen minutes until 6 gm. were taken. A final saline purge was given two hours after the last capsule of betanaphthol, on the last day of treatment. They report 85 per cent. of cures under this method, and no bad results from the large dose.

Gonzaga and Lima,² under the direction of Dr. Neiva of the sanitary service of São Paulo, Brazil, have slightly changed the Bayma-Alves treatment, to

render it more appropriate for field work on a large scale. In their method the preliminary purge is omitted, 6 gm. of betanaphthol are given (all at one time) early in the morning, and the dose is repeated for three successive days. Throughout treatment the patient receives only a light diet. Two hours after the last dose of betanaphthol, a saline purge is administered.

The report of Gonzaga and Lima is most encouraging. It states, in brief, that betanaphthol, in the heavy dosage which they used, was practically nontoxic, and was almost as efficacious as thymol—much more so than oil of chenopodium. From among 400 heavily infected cases treated by this method, 73.5 per cent. of cures were effected, and no severe toxic symptoms were encountered.

FIELD EXPERIMENTS WITH LARGE DOSES OF BETANAPHTHOL

In view of these interesting developments from betanaphthol treatments, and in order to test the efficacy and toxicity of large doses of this drug in the treatment of hookworm disease, a series of four experiments involving, in all, seventy-nine cases, was undertaken.

Experiment 1, carried on among a representative group of twenty-nine laborers (nineteen adults and ten children) on a coffee fazenda near Ribeirão Preto, São Paulo, Brazil, included nearly equal numbers of males and females. The children were between 6 and 14 years of age. The average hemoglobin of the group was 63.2 per cent. There were no cases of malaria on this fazenda, no palpable spleens among the group, none of the patients had had intermittent fever in at least ten years, and there was no record of malaria having been in the valley for many years. Gonzaga and Lima's field treatment dosage was adopted. For persons from 20 to 50 years old; one dose of 6 gm. of Mallinckrodt's sublimated betanaphthol was given on three successive mornings (with a graduated dose for children), in hard gelatin capsules with a little water. The final dose was followed after two hours by a saline purge. Symptoms produced by treatment were mild and transient; practically no vomiting occurred. A fresh specimen of urine was obtained every morning from each patient; no highly colored, bloody or smoky urine was found. The conclusion from Experiment 1 was that betanaphthol in 18-gm. doses is only slightly toxic.

Experiment 2 was carried out to obtain a larger series of cases. Nineteen adults and eleven children—Brazilians, mulattoes and negroes—on another fazenda were selected. There had been a few cases of malaria on this fazenda, in two years, and the group included two cases of severe anemia. The average hemoglobin was 69 per cent. The drug, dose and method of administration were all the same as in Experiment 1. Except for one case (Case 1), which will be discussed in detail later, no symptoms appeared as a result of treatment. Most of the patients worked in the harvest field throughout their three days of medication.

In Experiment 3, there were ten men, suffering from trachoma or other chronic eye disease, all of them field laborers from coffee fazendas in the interior of the state of São Paulo. The races chiefly represented were Italian and Brazilian. Sixty-seven per cent. was the average hemoglobin of the group, some members of which had suffered previously from malaria. The same method of treatment and the same

* From the Laboratory of Hygiene, Faculty of Medicine and Surgery of São Paulo.

1. Bayma and Alves: *Publicações do Serviço Sanitário do Estado de São Paulo*, N. S. 1: 65, 1918.

2. Gonzaga and Lima: *Publicações do Serviço Sanitário do Estado de São Paulo*, N. S. 1: 1, 1918.

dosage of betanaphthol were adopted as in the preceding experiments, but the drug was a Parke, Davis & Co. preparation, already mixed with charcoal, and put up in 0.5-gm. doses in gelatin capsules. Symptoms following treatment were extremely slight and transient. One characteristic was common to all ten cases—increase in the transitional cells. One man (Case 2, to be discussed later) suffered marked destruction of red blood cells, as revealed by blood and urine examinations.

Experiment 4 had as its chief object a careful study of the urine pigment which, Experiment 3 had shown, sometimes turned brown or black on standing. A new group of ten men received exactly the same treatment as that given in Experiment 3. Mallinckrodt's sublimated betanaphthol was used, as in Experiments 1 and 2. The symptoms following treatment, as in Experiment 3, were negligible, except in the case of one man (Case 4), whose history will be discussed later.

HISTORY OF CASES SHOWING BETANAPHTHOL POISONING

CASE 1.—As has been said, in Experiment 2 there was practically entire absence of symptoms following treatment, except in one instance: A mulatto, aged 10 years, son of a colonist on a fazenda in the far interior of São Paulo, had had severe malaria, from which he had never really recovered. He had nevertheless been obliged to work all day in the fields. When he came under observation, he was weak, pale and listless; his spleen was two finger breadths below the costal border, was firm and not tender, and his urine proved negative for albumin by the acetic acid test. The developments of this case were so striking, and in such contrast to those of the other cases in Experiment 3, that they are given in detail.

The boy was given 4 gm. of betanaphthol at 7 a. m., March 12, 1919; he had a good deal of nausea and abdominal pain, vomiting twice. During the afternoon he had three large soft bowel movements, and soon felt well enough to play about the yard. At midnight he awoke with severe abdominal pain, nausea and fever. The following morning he complained of intense abdominal pain, and vomited frequently. His abdomen was soft, except in the region of the spleen, where there was muscle spasm. The spleen, which was four finger breadths below the costal border, was very firm and tender. The pulse was slow and regular, and there was no fever. The urine was dark, but contained no fresh blood.

March 14, forty-eight hours after treatment, the condition of the boy was worse. During the night his urine had been red and scanty. A fresh specimen obtained during the morning was dark and smoky, but not blood-red. The albumin test by the acetic-acid method was strongly positive. The vomiting had stopped, but the abdominal pain had become more intense. The upper left quadrant of the abdomen had become exquisitely tender, and the muscles over this region were rigid. The lower border of the spleen could be determined only with difficulty. It was a full hand's breadth below the costal border, and was very firm.

During the next twenty-four hours the boy's condition grew much worse. He was markedly prostrated, with face drawn and pinched, and was evidently in severe pain. Lying constantly on his right side, with legs drawn up to his abdomen, he breathed rapidly in short, shallow, grunting, painful respirations. The upper left quadrant of the abdomen became so tender that he cried out when the skin over it was even touched. The other quadrants of the abdomen were not tender. The liver was not palpable, nor was there any tenderness over it. Because of the tenderness and rigidity in the upper left quadrant the spleen could not be palpated, and even percussion was unsatisfactory, although it was possible to demonstrate the lower point of splenic dullness, well below the umbilicus. The boy's temperature had risen to 39.2 C., the pulse rate was 120, and the respiration rate was 34. The conjunctiva showed jaundice in initial stages. The urine was

dark, but not bloody. The albumin test was strongly positive. A rupture of the spleen seemed imminent.

The following day—four days after the treatment—a slight improvement had taken place. There was less abdominal pain and less prostration. The temperature had dropped to 37.5 C., and the respiration to 30; the pulse remained at 120. The respirations were still shallow, but less painful. The whole abdomen was tense, with marked rigidity of the entire upper left quadrant. Palpation of the spleen was impossible, but the upper border to percussion was in the sixth interspace in the anterior axillary line, and the lower pole was below the level of the umbilicus. The icterus had increased slightly. The urine, which contained a trace of albumin, was dark and smoky, but its color had cleared considerably during the preceding twenty-four hours.

From this day (the fourth after treatment) the boy showed rapid improvement—the icterus disappeared, the albumin in the urine cleared away, and the spleen decreased in size. A blood film taken on May 16—four days after the betanaphthol treatment—showed a remarkable picture, the chief characteristic of which was the evidence of marked regeneration of red blood cells. Every third or fourth red blood cell was very large and deeply basophilic. There were two or three normoblasts to every microscopic field (oil immersion), and the nuclei of these normoblasts were of every describable shape. The white blood cells had also increased greatly in number, giving a picture, under the low power of the microscope, of a leukemia. A differential white blood cell count showed the proportions: leukocytes, 64 per cent.; transitionals, 24 per cent.; lymphocytes, 11 per cent.; eosinophils, 1 per cent., and nucleated red cells, 17 to every hundred white blood cells. Only one myeloblast appeared, and no myelocytes were seen. No malarial parasites were encountered.

The tenderness and muscle spasm in the upper left abdominal quadrant disappeared at the end of the seventh day. On the tenth day after treatment the boy was well enough to play about the yard, although his spleen was still three finger breadths below the costal border and was slightly tender. He had lost much weight.

This case could not be followed up with a careful clinical study, for the boy lived in a valley which was many miles from the railroad, and which was accessible only by a mule trail. Thus a careful uranalysis, a count of the red and the white blood cells, and a daily differential cell count, although important and desirable, could not be made. Nevertheless, even with those data that were available, the diagnosis was clear-cut—*acute enlargement of the spleen, following erythrocyte destruction*, caused by the administration of 4 gm. of betanaphthol.

The case showed that, although betanaphthol is usually innocuous, nevertheless under certain conditions it may be very toxic, with tremendous destruction of red blood cells. The question at once arose whether blood destruction might not occur in all cases treated with betanaphthol, although perhaps not in so severe a degree as to show objective symptoms. It is a well established fact that malaria renders the blood cells more fragile in some individuals, and it seemed possible that the previous malaria in this instance might have had some bearing on the patient's reaction to betanaphthol. These were points that could not be studied under field conditions, but required hospital supervision and carefully controlled laboratory experiments. I was able to fulfil these requirements, thanks to the kindness of Dr. A. Pedroso, pathologist of the Santa Casa Hospital of São Paulo, and Dr. Pereira Gomes of the ophthalmologic section. The latter allowed me to treat the hookworm patients of his wards.

CASE 2.—In Experiment 3, it will be recalled, the symptoms were negligible in the case of all patients but one. A small, poorly nourished negro, who was in the hospital with a diagnosis of glaucoma, and whose Wassermann reaction was posi-

tive, had had severe malaria two years before, but had suffered no recurrences. The preliminary urine examination was negative, and the blood examination revealed: hemoglobin, 70 per cent.; red cells, 4,900,000; white cells, 5,800; differential count: leukocytes, 70 per cent.; transitionals, 9 per cent.; lymphocytes, 13 per cent.; eosinophils, 8 per cent. The red cells were normal in appearance.

On the second day of treatment, the patient's urine, when freshly passed, was bright red, clear, acid and contained no albumin. It proved negative to a guaiac test, and gave a reduction with Fehling's solution, but not with bismuth. The sediment was negative. The original color of the urinary pigment turned to a much darker shade on standing. The following day (the last day of the treatment) a specimen of freshly passed urine was deep red, with the other characteristics of the previous day unchanged. The same dark red pigment, which did not give a guaiac test, continued to show in the urine for three more days, gradually disappearing, and apparently causing no irritation to the kidneys. One constant characteristic of this pigment—which will be discussed later—was that it turned much darker on standing.

Coincidentally with the urinary changes, a marked difference had occurred in the blood picture. Day by day the red cell count and the hemoglobin index were dropping, until, on May 3—the fourth day after the final dose of betanaphthol—the red cell count had been reduced from 4,900,000 to 2,400,000, and the hemoglobin from 70 per cent. to 51 per cent. The white cell count first increased, then dropped. The differential white cell count showed a marked increase in the transitional cells. Differential white cell count: leukocytes, 64 per cent.; transitionals, 14 per cent.; lymphocytes, 16 per cent.; eosinophils, 6 per cent.

The greatest changes had occurred in the red blood cells. There were large numbers of enormous, irregularly shaped, deeply basophilic red cells, many of them containing large, coarse granules. Nucleated red cells were common—one to every 100 white blood cells. No myeloblasts and no myelocytes were seen. Malarial parasites were not encountered.

Despite this marked destruction of red cells, the patient complained of nothing except thirstiness and a slight weakness. The spleen never became tender, nor was it ever palpable. The blood picture improved rapidly, and had practically resumed its former condition at the end of the fourteenth day, when the patient was discharged from the hospital. Chart 1 illustrates the blood picture as it changed from day to day.

CASE 3.—In Experiment 3, the patient evidenced a blood change corresponding to that in Case 2, although much less severe. The preliminary blood picture showed 67 per cent. hemoglobin, a red cell count of 4,970,000 and a white cell count of 9,900, with transitionals 9 per cent., lymphocytes 17 per cent., and eosinophils 4 per cent. The entire blood picture was: hemoglobin, 67 per cent.; red cells, 4,970,000; white blood cells, 9,900; differential count: leukocytes, 70 per cent.;

transitionals, 9 per cent.; lymphocytes, 17 per cent.; eosinophils, 4 per cent. The red cells appeared normal.

May 1, the day following the patient's last dose of betanaphthol, the blood picture was: hemoglobin, 62 per cent.; red blood cells, 3,800,000; white blood cells, 8,000; differential count: leukocytes, 63 per cent.; transitionals, 14 per cent.; lymphocytes, 11 per cent.; eosinophils, 12 per cent.

The red cells occasionally showed very large, irregularly shaped erythrocytes, some of which were stippled, and some deeply basophilic. Three normoblasts were seen. The increase in transitionals—as compared to the condition in the original blood picture—is to be noted. This was a characteristic that was common to all ten cases in Experiment 3.

This day, May 1, proved to be the turning point, for the blood rapidly resumed its normal characteristics, so that eight days after treatment it presented a picture practically identical

with the one seen in the preliminary examinations. The urine in this case never contained red pigment, although it turned dark brown on standing. Albumin and guaiac tests in the urine proved negative, but Fehling's solution was reduced during the three days of treatment. The boy had no symptoms whatever during the treatment.

CASE 4.—The one case in Experiment 4 in which symptoms were marked was that of a negro, aged 35, who was in the hospital for a cataract operation. Although he had never fully recovered his strength since a malaria attack six years before, his general condition at the time of examination was good. The urine proved negative, the spleen was not palpable, the red blood cells appeared normal, and no malarial parasites were seen. Chart 2 shows the detailed changes in the red cells, white cells and hemoglobin from the time of first treatment until more than two weeks later.

The patient's condition at the time of preliminary examination was good—urine negative, spleen not palpable, red blood cells normal in appearance, and no parasites to be seen. The hemoglobin was 73 per cent., red blood cells were 4,400,000, white blood cells, 10,800, leukocytes 62 per cent.,

and eosinophils 11 per cent. May 13, the first medication—6 gm. of Mallinckrodt's betanaphthol—was given, and resulted in some nausea and vomiting. May 14, the patient's condition being normal, the dose was repeated. That same day, the man felt very ill—his symptoms including severe headache—and he continued so all through the night.

The following morning, May 15, he was prostrated; the pulse was weak (96), and the temperature was subnormal (36.8 C., or 98.2 F.). Icterus had begun, and the spleen was readily palpable. The urine was thick, black and viscid, and albumin and guaiac reactions were strongly positive. The blood was thick and viscid, and the red blood cells were badly broken. It will be noted, by reference to the chart, that on this day (May 15) the high point (81 per cent.) was reached by the hemoglobin, and that for the next five days the hemoglobin percentage dropped steadily, until it reached the low point (17 per cent.), May 20. May 16, the patient was worse. The urine was dense, purple and sticky, with a

Chart 1.—The blood in Case 2.

heavy, gray sediment; vomiting was persistent, the icterus had deepened, the spleen was enlarged, and the abdomen in the region of the gallbladder was very tender. The hemoglobin index and the red cell count were falling rapidly.

May 18, the patient's condition grew desperate, the only encouraging feature being practically entire elimination of destroyed red cells from the blood. Hemoglobin was only 22 per cent. and red cells numbered only 1,500,000. A stool, obtained by enema, was a coal-black mass, sticky and viscid. May 19, the low point was reached by the red blood cells; the icterus had deepened slightly; the gallbladder was still tender; and there was a low grade fever of 38 to 38.5 C. (from 100.4 to 101.3 F.). The blood picture was improving rapidly, however, and the urine was quickly clearing.

From May 20—seven days after the first dose of betanaphthol—a slow, gradual improvement began, as evidenced by clearing of the urine, lessening of the icterus, and decrease in the size of the gallbladder, liver and spleen. By May 22, the hemoglobin had increased to 22 per cent., and the red blood cells to 1,600,000, with the differential proportions unchanged. The spleen was not palpable, and the gallbladder was readily felt but still tender.

May 29—two weeks after the betanaphthol was administered—the patient was improving slowly. There was still nausea, but the icterus had gone, and the urine was negative. The gallbladder was still palpable. A blood picture showed the red cells to appear, generally speaking, entirely normal. The most striking feature was the diminution in the proportion of lymphocytes. They had dropped from 15 per cent. (the original picture) to 7 per cent., having declined steadily throughout the period in question.

CONCLUSIONS

The four experiments prove that betanaphthol in 6-gm. doses, given on three successive days, may produce a severe toxic effect similar to that caused by benzol (benzene, C_6H_6), in that it specifically attacks the red blood cells. In the four cases of betanaphthol poisoning reported, while the symptomatology varied greatly, the essential pathology common to all cases was simply a destruction of red blood cells with, perhaps, in the severe cases a destruction of the blood-forming cells in the bone marrow. It is hard to explain how the betanaphthol destroys the red blood cells, and why seventy-five of the cases which I treated showed no symptoms, while four became victims of the drug's toxic action. Comparison of the cases and of their history previous to the betanaphthol treatment would certainly seem to indicate, first, that the intoxication shown by the poisoned cases was not due to their greater intestinal absorption of the drug; second, that the size of the dose was not proportionate to the degree of intoxication, and third, that the degree

of previous anemia in the patient apparently had nothing to do with the toxic effect of the drug. The experiments also showed that the drug had little or no effect on normal kidneys. In certain cases, to be sure, there was much albumin in the urine, with many casts; but this condition was due to the elimination of the waste products from the blood.

Finally, the following definite conclusions concerning the toxic action of betanaphthol were arrived at as a result of the experiments that have been described:

1. Large doses of betanaphthol (18 gm. for adults) used in the treatment of seventy-nine cases of hookworm disease produced very severe toxic symptoms in two cases, and also produced marked changes in the blood cells of two other cases.

2. The toxic action of betanaphthol in these four cases was a destruction of the red blood cells. The drug selected the red blood cells and destroyed them in great numbers, with resultant severe anemia, icterus, enlargement of the spleen and liver, enlargement of the gallbladder and hemoglobinuria. The white blood cells apparently were not destroyed by the drug. The liver, spleen, kidneys and other organs of the body were not affected primarily, but were markedly affected secondarily, because of the anemia, and because of the injurious effects produced by the elimination of large numbers of destroyed red blood cells.

3. The type of cases that are most susceptible to the toxic action of betanaphthol poisoning has not been determined. In all three of the severe cases of poisoning there was a history of recent malaria. It is probable that those cases in which the red blood cells are rendered more fragile

by recent malaria are more susceptible to betanaphthol poisoning.

4. Betanaphthol, in 18-gm. doses, is so toxic that it cannot be recommended for general use in the treatment of hookworm disease.³

A CARDIOVASCULAR RATING AS A
MEASURE OF PHYSICAL FATIGUE
AND EFFICIENCY*EDWARD C. SCHNEIDER, PH.D.
MIDDLETOWN, CONN.

The need of a measure for physical efficiency whereby degrees of fatigue, physical fitness and health may be determined has been felt alike by the medical profession and instructors in physical education and school hygiene. Of late, the newly awakened interest in industrial efficiency has shown that we lack satisfactory and reliable tests of fatigue. Experience with the aviator during the war also emphasized the need of some easily applied reliable physical efficiency test. Some aviators gradually underwent physical and nervous deterioration, the result of the wear and tear of the air work, or sometimes of dissipation, which made them less reliable in handling the aeroplane and frequently ultimately led to a crash. These aviators at times developed a disinclination to fly, but would not confess it because of the fear of being considered "yellow." To single out such men, the flight surgeon required the aid of a dependable test.

Unquestionably, the most satisfactory test for fatigue and loss in physical fitness would be one that eliminates the "personal equation" of the examiner and the anxiety and dishonesty of the patient. Replies to questions concerning symptoms and habits are often misleading because of a preformed opinion by the examiner or because the patient is incapable of self-analysis and accurate description of his experiences. Furthermore, for personal reasons some men would prefer to mislead the examiner, and the test should not, therefore, demand much cooperation and attention from the patient.

The functional changes of the body brought about by regular physical training give the basis for a number of physical efficiency tests. The attention of trainers and athletes, as well as of physiologists, has naturally been directed to these. A brief review of the conclusions regarding the physiologic changes which occur as a result of improved physical condition will suggest possible tests for degrees of health and fitness.

Certain differences between active and inactive animals throw light on these functional variations. The wild hare, which lives an active life in the open, and the wild rabbit, which lives an inactive life in seclusion and does not venture far from its burrow, have been compared by Dreyer¹ of Oxford University. He found that a wild hare has double the blood volume, 30 per cent. more hemoglobin and three times more heart muscle than a wild rabbit of the same weight. The rate of heart beat of the wild hare is about 68, and of the wild rabbit about 200 per minute. The respiration rate of the hare is between 18 and 20, and of the rabbit about 50 per minute. Furthermore, the meat of the hare is dark, and that of the rabbit light in color. No doubt, similar differences exist between an athlete and a sedentary worker, and there is reason to believe that these functional differences vary to some extent as the health and fitness of the individual person vary.

The cardiovascular changes during altered physical fitness have been studied most, and it is these that are

considered in this paper. The tests here discussed should not be confused with functional heart tests. We are concerned with the cardiovascular changes only so far as they give evidence of fatigue and health changes in the body.

THE PULSE RATE AS A CRITERION OF HEALTH

(a) *The Postural Rates.*—Cook and Pembrey,² while finding considerable variation in the pulse rate of different healthy individuals, showed, however, more frequently a slow rate in men trained for muscular work. From his extensive experience, Meylan³ concluded that a horizontal posture pulse rate between 40 and 80 and a vertical posture rate between 50 and 90 were favorable health signs. McCurdy,⁴ from a study of boys passing through the adolescent changes, decided that the heart rate serves as a fair indication of condition; a high heart rate indicates poor condition, and a heart rate with wide variations between the horizontal and standing positions suggests a poor vascular adjustment.

During repeated periods of training of a single subject, Dawson⁵ found that training slowed the resting pulse rate as much as 9 beats per minute and that this especially influenced the noon and afternoon pulse. Thus the form of the diurnal curve was slightly altered. He also found that acute infection caused an increase in the pulse rate, but this was much less pronounced in the trained than in the untrained man. In young men, the normal average pulse rate has been reported to be 78.9 standing, 70.1 sitting and 66.6 lying. The continued practice of some form of exercise, such as rowing, extending over a period of years may progressively lower the rate of heart beat. Thus Michell⁶ found the average rate of the athlete's pulse during the first year of training was 69, in the second year, 64.5 and in the third year, 56.8. According to Lindhard,⁷ not only is the pulse less frequent, but the output of the heart per minute is slightly larger in the trained than in the untrained man.

All available evidence indicates that with improvement in physical fitness the heart beats less frequently and more efficiently. It follows, therefore, that the pulse rates in the reclining and standing postures may at times give useful hints as to the degree of fitness and health. That the altered physical condition may not be evidenced by pulse rate changes in both of these postural positions was demonstrated by Boney,⁸ who found in some tired, listless, depressed and fatigued patients that the pulse rate was normal while lying down but was abnormally rapid on standing; in several the standing rate was as high as 130 or 140 beats per minute.

(b) *Pulse Rate Increase on Standing.*—The difference between the pulse rates in the standing and reclining postures has been found to be a useful index of physical fitness. According to Vierordt,⁹ the average postural increase is from 12 to 14 beats. Crampton¹⁰ reported that in vigorous subjects the heart rate may not increase on standing, while in wearied subjects it may increase as much as 44 beats per minute. Meylan³ believes a standing increase of not more than

1. Dreyer, cited by Flack, M., and Hill, L.: *Text-Book of Physiology*, New York, Longmans, Green & Co., 1919, p. 79.

16 beats is a favorable sign of physical efficiency. Parkinson¹¹ recently reported that in twenty healthy soldiers an average increase of 10 beats was noted when the recumbent and standing rates were compared. Geigel¹² considers that a variation of more than 30 between lying and standing pulse rates indicates weakened heart function. It is now recognized that in states of debility the postural difference may be as much as from 30 to 50 per minute. A slow horizontal and a slow vertical postural pulse rate with a small difference between the two are usually signs of excellent health.

(c) *Exercise Pulse Rate.*—According to Bowen,¹³ the rapidity of the pulse during exercise is chiefly determined by (1) the speed of movement; (2) the resistance encountered; (3) the condition of the individual, and (4) age. He¹⁴ also pointed out that pulse rate counts made after exercise are worthless for comparison, unless the count is made at exactly the same period in each case, and the subject is placed in exactly the same position and assumes the same degree of relaxation and repose.

The increase in the pulse rate after a certain amount of work is greater in an untrained than in a trained person. Hartwell and Tweedy,¹⁵ comparing athletic and nonathletic women, found that running up and down stairs accelerated the heart rate an average of 10 beats more in the nonathletic women. Cotton, Rapport and Lewis¹⁶ believe that the average height to which the pulse rate is raised at the cessation of effort may be taken as a gage of the degree of distress produced, and that the amount of distress is determined by the degree of health. Similar conclusions have been reached by many students of the effects of exercise on acceleration of the pulse rate.

(d) *The Decline in Pulse Rate After Exertion.*—A widely recognized sign of physical condition is the time required by the pulse rate to return to normal after effort. Flack and Bowdler,¹⁷ from a study of the reactions following stepping on a chair five times in fifteen seconds, conclude that the heart rate in the healthy subject should not increase more than 25 beats and should return to normal within thirty seconds. Meakins and Gunson¹⁸ report that after a climb of twenty-seven steps at a brisk walk, the pulse rate returned to normal within one minute in healthy subjects, while in patients it required as much as five minutes.

It should be emphasized that while the several pulse rate criteria of fitness may all be found in a single person, not one or even any two of them is found to be an absolute test. In forming a judgment as to the physical condition of a man it is best to consider together the postural rates, the increase on standing and after exercise, and the time required for the rate to return to normal after exercise.

THE ARTERIAL BLOOD PRESSURE AS A CRITERION OF CONDITION

(a) *The Normal Arterial Pressures.*—Although the arterial pressures have received much attention, the determination of the pressures of a person at rest

offers little of value in estimating the physical condition of the young man. Meylan³ considers systolic pressures for the horizontal posture between 110 and 140, and for the vertical position between 110 and 150 mm. of mercury as favorable signs. Dearborn¹⁹ believes that adequate physical training raises the blood pressure. He obtained an average of 114 in trained and 108 in untrained women. Dawson⁵ has recently shown that the effect of training on the resting blood pressure is neither striking nor constant. Bainbridge²⁰ has written that "the systolic arterial pressure, according to most observers, is not higher during rest in trained than in untrained men."

Opinion as to the value of the diastolic and pulse pressures is not as clearly crystallized as it is regarding the systolic pressure. Hypotension in systolic or diastolic pressure occurs in weak patients.

(b) *The Postural Changes in Arterial Pressures.*—The hydrostatic effects of posture and the manner in which the splanchnic vasomotor mechanism compensates for these are well known. Normally, when man changes from the reclining to the standing position, the splanchnic vasomotor tone overcompensates the hydrostatic effects of gravity. In normal subjects the systolic blood pressure is about 10 mm. higher in the standing than in the recumbent posture. Erlanger and Hooker²¹ found that on standing there might be either a slight rise or fall in the brachial systolic pressure. According to Hill,²² any influence which weakens the splanchnic vasomotor mechanism interferes with the compensation. Sewall²³ has shown that individuals in whom there is excessive gravitation of the blood to the limbs and splanchnic area on standing are victims of physical weakness and nervous instability and often suffer from headache, dizziness or tinnitus in the erect posture. That the systolic pressure falls in persons weakened by dissipation, overwork, lack of sleep, or disease was recognized by Crampton in his "blood ptosis test" for physical fitness. Crampton¹⁰ demonstrated that a subject might, when standing, show weakness by a decrease in the systolic pressure or by a large increase in the heart rate. Recently, Sewall²³ has pointed out that a weakened patient on standing may fail to show the systolic drop, but instead may have an inordinate rise in diastolic pressure. He employs this rise in diastolic pressure and low levels of pulse pressure as measures of fitness.

MEANS OF MEASURING PHYSICAL EFFICIENCY

The foregoing observations on the cardiovascular changes that occur with training and with weakness suggest means of measuring fatigue, staleness and weakness. A pulse rate more rapid than the average in the reclining and standing postures, a large acceleration on standing and after exertion, a slow return to normal after exercise, and a systolic pressure that fails to rise but falls when the subject stands, indicate fatigue or weakness.

In 1913 and 1914, three physical efficiency tests were reported that used some or all of these changes. Crampton's¹⁰ "blood ptosis test" is a vasomotor efficiency test that is intended to show the beneficial or depressive effect of various conditions supposed to affect the health. It takes account of the differences between the pulse rates and the systolic pressures in

the horizontal and vertical postures. The usual range of systolic pressure variation is from +10 to -10, and the heart rate increase from 0 to 44. It was determined that a decrease of 1 mm. in systolic pressure was equivalent to an increase in heart rate of approximately 2 beats. By statistically balancing the ranges of systolic pressure and pulse rate and assigning equal percentages to equal ranges, a percentage scale of fitness was established.

Meylan,³ although not attempting to evaluate, finds that efficiency may be judged by (1) general condition as shown in weight, color of skin and general appearances such as firm, vigorous muscles; (2) pulse rate in the horizontal and vertical positions; (3) systolic blood pressure in the horizontal and vertical positions, and (4) heart reaction after the exercise of hopping 100 feet. Favorable signs were considered to be a horizontal pulse rate between 40 and 80, a vertical rate between 50 and 90, and a standing increase of not more than 16; a horizontal blood pressure between 100 and 140, and a vertical pressure between 110 and 150, with a difference of 10 or more; an exercise increase in pulse rate of less than 100 per cent. and a recovery of more than 80 per cent. in a minute.

Foster's²⁴ efficiency test made use of the standing pulse rate, the rate immediately after running in a fixed place for exactly fifteen seconds at the rate of 180 steps per minute, and the rate forty-five seconds after the work ceased.

Crampton's test was employed with the aviators at Hazelhurst Field, but was found to be unsatisfactory because of the fact that physical deterioration may be manifest in various ways in the cardiovascular mechanism. The test neglects four of the available factors. A similar criticism may be made of Foster's method. A statistical study of several hundred cases led to the abandonment of both of these methods.

POINT SYSTEM FOR GRADING CARDIOVASCULAR REACTIONS

When it becomes necessary to weigh data from six sets of observations, it is difficult to evaluate them properly and to avoid giving undue weight to a single factor. If it is true, as it seems to be, that weakness may show itself differently in individual cases, then a centering of the attention only on the postural systolic blood pressure changes or on the amount of acceleration of the pulse rate in exercise would result in the overlooking of some cases of weakness. In order to avoid the disposition to stress one or two of the factors that give evidence of physical deterioration, and to recognize equally all six factors, we have used a system of scoring the tests wherein each of the cardiovascular changes is rated according to a scale that evaluates the condition or change. The grading of performance must of necessity be arbitrary and, therefore, is held by some to be objectionable. Nevertheless, as was stated earlier, the "personal equation" of the observer often weighs too heavily where comparisons are made. A mathematical system of grading can in large measure eliminate the personal factor.

The scoring scheme we have used recognizes that fatigue or derangement may be evidenced in the high heart rate during reclining, during standing; in the number of beats the heart rate increases when the standing and reclining postures are compared; in the acceleration in the pulse rate after exercise; in the

time taken by the pulse to return to normal, and, lastly, in the rise or fall in the systolic blood pressure on standing. This scheme uses in part a plan proposed by Dr. J. H. McCurdy for rating infantry men in cardiovascular and neuromuscular efficiency. The scores for each of the six items range from +3 to -3. A perfect score, the sum of the value given to each of the six items, is 18. The values as assigned appear in Table 1, Parts A, B, C, D, E and F. In using the table for scoring, Parts A and B, also C and D, must always be used together. Thus, if an individual has a pulse rate increase of 15 beats (see Part B) on standing and his reclining rate was 60 (see Part A), he is graded 3 on his standing increase. However, if his reclining rate had been 100, then a standing increase of 15 would have been scored 0.

PROCEDURE IN MAKING OBSERVATIONS

1. The patient reclines for five minutes. (a) The heart rate is then counted for twenty seconds. When two consecutive twenty second counts are the same,

TABLE 1.—POINTS FOR GRADING CARDIOVASCULAR CHANGES

A. Reclining Pulse Rate		B. Pulse Rate Increase on Standing				
Rate	Points	0-10 Beats, Points	11-18 Beats, Points	19-26 Beats, Points	27-34 Beats, Points	35-42 Beats, Points
50-60	3	3	3	2	1	0
61-70	3	3	2	1	0	-1
71-80	2	3	2	0	-1	-2
81-90	1	2	1	-1	-2	-3
91-100	0	1	0	-2	-3	-3
101-110	-1	0	-1	-3	-3	-3

C. Standing Pulse Rate		D. Pulse Rate Increase Immediately after Exercise				
Rate	Points	0-10 Beats, Points	11-20 Beats, Points	21-30 Beats, Points	31-40 Beats, Points	41-50 Beats, Points
60-70	3	3	3	2	1	0
71-80	3	3	2	1	0	0
81-90	2	3	2	1	0	-1
91-100	1	2	1	0	-1	-2
101-110	1	1	0	-1	-2	-3
111-120	0	1	-1	-2	-3	-3
121-130	0	0	-2	-3	-3	-3
131-140	-1	0	-3	-3	-3	-3

E. Return of Pulse Rate to Standing Normal after Exercise		F. Systolic Pressure, Standing, Compared with Reclining	
Seconds	Points	Change in Mm.	Points
0-60.....	3	Rise of 8 or more	3
61-90.....	2	Rise of 2-7.....	2
91-120.....	1	No rise.....	1
After 120: 2-10 beats above normal	0	Fall of 2-5.....	0
After 120: 11-30 beats above normal	-1	Fall of 6 or more	-1

this is multiplied by 3 and recorded. The score is noted according to Part A, Table 1. (b) The systolic blood pressure is next taken by auscultation; two or three readings are made as a check.

2. (a) The patient stands at ease for one or two minutes to allow the pulse to assume a uniform rate. When two consecutive twenty second counts are the same, this is multiplied by 3 and recorded. The score is obtained by use of Part C, Table 1. The difference between the standing and reclining pulse rates is scored then by use of Part B, Table 1. (b) The standing systolic pressure is next taken. The difference between this and the reclining systolic pressure is then scored by Part F, Table 1.

3. The patient next steps on a chair about 18 inches high, five times in fifteen seconds timed by a watch. To make this test uniform, he stands with one foot on the chair at the count one; this foot remains on the chair and is not brought to the floor again until after the count five. At each count he brings the other foot on the chair and at the count "down" replaces it on

the floor. This should be timed accurately, so that at the fifteen second mark both feet are on the floor. (a) Immediately, while he stands at ease, the pulse rate is counted for fifteen seconds; this is multiplied by 4 and recorded. (b) Counting is continued in fifteen second intervals for two minutes, record being made of the counts at 60, 90 and 120 seconds.

The data from *a* will be scored by Part D, Table 1, taking the difference between this exercise pulse rate and the standing rate. The data in *b* are scored according to Part E, Table 1.

This system of scoring men as to physical fitness is now being used by flight surgeons in their work among aviators, and is applied at the Medical Research Laboratory at Mitchel Aviation Field on Long Island.

That there may be value in assembling the circulatory data under such a point system is indicated from an analysis of fifty-four cases of aviators who, when examined by the medical officers of the departments of the laboratory, were found to be ailing and physically below standard. The medical examinations included an overhaul by the internist, neurologist, ophthalmologist, and ear, nose and throat expert. The medical findings include a large variety of conditions, the majority being common to any group of men and in no way characteristic of aviators.

That which was of greatest interest in this analysis was the final efficiency score of each patient. The distribution of the cases is shown in Table 2.

TABLE 2.—EFFICIENCY SCORE IN FIFTY-FOUR CASES

Points	No. of Cases	Per Cent.
0 or less.....	2	3.7
From 1 to 3.....	9	16.6
4 to 6.....	15	27.8
7 to 9.....	22	40.7
10 to 12.....	3	5.6
13 to 15.....	3	5.6
16 to 18.....	0	0.0
Total.....	54	100.0

Only six of the fifty-four cases had a score of 10 or better, while 88.8 per cent. had scores ranging between 9 and —1. These figures seem to indicate that a score of 9 or less is characteristic of physically unfit men.

On the assumption that a score of 9 or less gives indication that the clinician may find something wrong with the patient, we have listed all men among a group of 150 men who had a low score. In this group there were forty-six who scored 9 or less.

The medical examiners working independently, and without the cardiovascular data available to them, recorded abnormal conditions in thirty of the forty-six men. Thus, when working independently, 65.2 per cent. of the group of forty-six with low scores by the cardiovascular efficiency test were found by others to be below standard. Two of the men were unfit because of excessive smoking, and one had recently been on a drunken spree. The neurologist reported five as stale and nervously unbalanced, the internist alone found five unfit, six were tonsil or local infection cases, and the remainder were found wrong by at least two of the medical departments.

This point system of scoring men as to health and physical fitness by the cardiovascular reactions is easily applied. It has the advantage of stimulating men to attempt to improve the score by exercise and proper living. It is suggested that a score of 9 or less

gives reason for an overhaul of the patient by a clinician. Aviators with a low score might well be called back for further examination and observation. A poor score suggests a search for a cause. The cause may be disease or unhygienic living.

THE DIAGNOSIS AND PROGNOSIS OF LOSS OF VISION FROM ACCESSORY SINUS DISEASE*

LEON E. WHITE, M.D.

BOSTON

Having for the past three years made a study of blindness originating in the accessory sinuses, I wish to present some of the results, which may be of interest to the profession and possibly of some benefit to humanity. The question has been asked many times what findings warrant operative interference: in other words, how to arrive at a correct diagnosis. This paper is devoted to this phase of the subject, although some space is given to the prognosis.

There are various types of accessory sinus blindness, some of which will recover spontaneously, while others will result in permanent loss of vision unless prompt and proper attention is given. Etiologically they are generally divided as: (1) those due to a direct spreading of the infection to the sheath of the optic nerve; (2) those due to the toxemia from infection in the sinuses, and (3) those due to hyperplasia.

It is usually easy to diagnose the first two types either from inspection or from the roentgenograms, although pus not possible to detect previously is occasionally found on operating. As the nasal and roentgen-ray examinations are frequently negative in the third, the hyperplastic, type, when the middle turbinate is not involved, the diagnosis is much more difficult. The same line of reasoning, however, is equally applicable to all when a definite diagnosis cannot be made.

Hyperplasia has been defined as a rarefying osteitis associated with inflammatory swelling, and fibrous thickening of the mucous membrane lining the accessory sinuses. Its pathology has always seemed to me rather obscure. Many specimens have been sent to the laboratory, but nothing of interest has been discovered. Dr. Verhoeff, the pathologist, says that they are more or less traumatized in removal, and when they are decalcified whatever changes may have occurred seem to be destroyed. In one of the last cases, for example, the posterior ethmoid was filled with a thick, gelatinous looking membrane, which I was able to remove entire. It was carefully handled and sent to the laboratory apparently in good condition, and I had high hopes of getting some valuable information; but the report, as usual, was negative. Dr. Sluder sent many of his specimens to Dr. Jonathan Wright, who was able to build up from these and some of his own a fairly consistent explanation of the process taking place in hyperplasia; but even he, at the end of his discussion, said:

It would probably be difficult to find an adult individual in a temperate or cold climate who does not present an example of this bone change within his nasal chambers which I have a right to call pathological. It is only exceptionally that the symptoms to which it gives rise are sufficient to cause him to seek relief.

* Read before the Section on Laryngology, Otology and Rhinology at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

From the foregoing it is readily seen that many of these cases have a condition so elusive as to be difficult of detection either microscopically or macroscopically. In looking into these noses one is disappointed in not finding much, if anything, pathologic. A most careful inspection of the size and position of the middle turbinate should be made, as it will frequently be found to be normal anteriorly but to widen posteriorly. The position of the nasal septum is also of importance in its posterior aspect, as the middle turbinate is frequently wedged between it and the ethmoidal wall. In many of these cases there will be found some slight obstruction to the drainage from the posterior sinuses. The changes are, however, difficult to detect, and negative reports have been given by very good rhinologists even when a markedly pathologic condition was found on operating. It is always a disappointment to the ophthalmologist when pus cannot be found and the roentgenograms are negative. It is difficult to convince some that there is such a thing as hyperplasia; but case after case has demonstrated that pressure sufficient to cause atrophy of the nerve can take place in a nose that on both inspection and roentgen-ray examinations showed practically nothing abnormal.

Toxemia is frequently the cause of blindness, and its origin should be carefully investigated before advising the opening of the sinuses. Teeth, tonsils, accessory sinuses, intestinal autointoxication, alcohol, tobacco, syphilis, etc., must all be considered. An interesting illustration of the necessity of this occurred in the clinic at the infirmary, when I was hurriedly called to examine a nose in a case of recent loss of vision. In questioning the patient it was learned that one of his friends in the furniture business had given him some alcohol with which to rub his chest. The alcohol was found to be of the wood variety, and the vision returned after its discontinuance.

The possibility of the loss of vision being due to pituitary disease must likewise be considered, and careful study made of the plates of that region. I have seen at least a dozen of these cases. Two were malignant. In a third there had been a complete bilateral ethmoid and sphenoid exenteration, which could have been avoided had the plates been inspected. It has been my practice to have each case thoroughly investigated; that is, to have a medical, neurologic, dental, Wassermann and roentgen-ray examination in addition to the ophthalmologic. If these findings are negative and the condition of the eye is unimproved or becoming progressively worse, I advise the immediate removal of the middle turbinate and the opening of the posterior accessory sinuses.

While it is a source of satisfaction to operate on patients with a marked nasal pathologic condition, nevertheless one should realize that unless some definite explanation for the loss of vision can be found elsewhere, its most probable origin is in the sinuses. The diagnosis of accessory sinus disease in cases of practically negative nasal findings is largely made by exclusion.

THE PROGNOSIS

It is well known that cases of blindness from accessory sinus disease recover spontaneously. Four of my patients have told of previous attacks in which the eye was blurry for two or three days and the vision defective, but from which they recovered without treatment. One of them had a second attack a year

later and delayed so long before seeking advice, expecting the eye to recover as before, that optic atrophy resulted. Thus it is unfortunate in a sense that these cases tend to recover spontaneously, as permanent injury may result while waiting. This is especially true when there is complete loss of vision.

There are two factors that enter largely into the prognosis: (1) the question of time before the patient seeks relief, and (2) the question of the degree of blindness. As to the question of time, I have endeavored to determine from the cases studied how long an interval could elapse beyond which there would be danger of permanent impairment of vision—in other words, how long one can treat or watch a case before advising operative interference.

The chronological summary shows this.

In the twenty-five cases tabulated, two patients recovered under local treatment, one of four days' duration with vision 20/40, and the other of four months' duration with vision 20/70 (Cases 3 and 20).

Five operations were performed within the first week and normal vision was obtained in all (Cases 2, 9, 9a, 9b and 17).

Of the five patients operated on within two weeks, two recovered with normal vision, two with vision 20/20—but slight pallor of the nerve, and one with a vision of fingers at 6 inches and optic atrophy (Cases 5, 7, 18, 24 and 25).

In the four cases in which the patients were operated on between the second and fourth weeks, normal vision, but with some pallor of the disk, was obtained in one. The others, however, were all improved (Cases 14, 15, 18 and 19).

Four patients were operated on between the first and second months. One recovered with normal vision, another with 20/20—and some pallor of the disk. In the other two there was optic atrophy with no improvement in one and but slight improvement in the other (Cases 4, 6, 8 and 22).

Of the five cases of over two months' duration there was no improvement in two. In the other three the improvement was so slight it was almost negligible (Cases 10, 12, 13, 16 and 21).

From the foregoing summary one can say with some degree of assurance that unless a case shows improvement under treatment before the end of a week, there is danger of permanent loss of vision unless the pressure on the nerve can be relieved. In Case 24 this actually occurred in eleven days, this patient refusing to have anything done until the social service took hold.

In cases of more than two months' duration, little can be expected. It is probable that the progress of the disease can be checked if it is due to some infection in the sinuses.

As to the degree of the loss of vision: In the six cases in which there was complete blindness, two patients, with blindness of eight and ten days' duration, recovered nearly all their vision, but there remained pallor of the nerve. In one case of four weeks' standing, good vision was obtained, but there was some pallor. Two were unimproved, while the third was able only to count fingers at 3 feet (Cases 6, 10, 14, 22, 23 and 24).

Thus, the demand for early operative inference in the cases of total loss of vision is much more imperative than when the loss is but partial. It would seem the wiser course to err here on the side of advising operation too soon, and possibly unnecessarily, than to

risk a patient becoming permanently blind through delay.

The last three cases have not been previously reported, so it may be of interest to give these somewhat in detail:

REPORT OF CASES

CASE 23.—N. S., a man, aged 30, referred by Dr. Alexander Quackenboss at the infirmary, Jan. 9, 1920, with a diagnosis of retrobulbar neuritis, right, of seven days' duration, had

noticed a slight pain and blurring of the right eye, two weeks previously, following a severe cold. The haziness increased so that at one time he could not even perceive light. On admission he was able to distinguish finger movements in the temporal field at 1 foot. The edges of the right disk were slightly indistinct and the smaller blood vessels rather prominent. The septum was deflected; and while the anterior end of the right middle turbinate was small, the posterior portion was large and obstructive. Roentgenograms and neurologic, physical, dental and Wassermann tests were all

SUMMARY OF INDIVIDUAL FINDINGS

Case	Referred by	Eye	Diagnosis	Duration	Nasal Findings	Roentgen-Ray Report	Vision before Operation	Operation	Vision after Operation	Pathologic Findings	Comment
1.	Dr. H. B. Chandler....	Left	Chronic retrobulbar neuritis	1 year	Pus about sphenoid	Ethmoids obscured	Light perception	None	Unimproved	Pus	
2.	Dr. W. J. Daly.....	Both	Acute retrobulbar neuritis	7 days	Negative	Asymmetry of sphenoid	2/20	Left mid. turb. and sphenoid	Normal	Hyperplasia	
3.	Dr. F. I. Proctor.....	Both	Acute retrobulbar neuritis	3 days	Hypertrophied middle turbinates	Sphenoids hazy	Rt. 20/30 Left 20/40	Local treatment	Normal	Hyperplasia	Removed left middle turb. after vision was normal
4.	Dr. F. H. Verhoeff..... (M. C. E. & E. I.)	Both	Retrobulbar neuritis with some optic atrophy	6 wks.	Negative	Left sphenoid obscured	Rt. 2/200 Left shadows	Both mid. turbs., post. ethmoids and sphenoids	Rt. fingers 2 ft., Left fingers 3 ft.	Pus and gran. in sphenoid	Optic atrophy
5.	Dr. R. C. Maekenzle.... (M. C. E. & E. I.)	Both	Acute optic neuritis	2 wks.	Negative	Negative	Rt. fingers 1 ft., Left 20/200	Right mid. turb. and sphenoid	Normal	Hyperplasia	Slight pallor of disk
6.	Dr. P. H. Thompson... (M. C. E. & E. I.)	Left	Acute retrobulbar neuritis	6 wks.	Def. septum	Negative	Light perception	Sept., mid. turb. and sphenoid	20/20—	Hyperplasia	Slight pallor of disk
7.	Dr. Alex. Quackenboss (M. C. E. & E. I.)	Both	Optic neuritis	10 days	Hypertrophied middle turbinates	Negative	Rt. nil, Lt. fingers	Both mid. turbs. and sphenoid	Normal	Hyperplasia	Slight pallor of disk
8.	Dr. F. M. Spalding..... (M. C. E. & E. I.)	Both	Optic neuritis	6 wks.	Negative	Negative	Rt. light percep., Lt. fingers 3 ft.	Septum, rt. mid. turb. and sphenoid	Normal	Carious molar; dis. antrum	
9.	Dr. F. H. Verhoeff..... (M. C. E. & E. I.)	Left	Papillitis	6 days	Negative	Negative	20/200	Left mid. turb., post. ethmoids and sphenoid	Normal	Pus and gran.; carious tooth	Exophthalmos
9a.	Dr. F. H. Verhoeff..... (M. C. E. & E. I.)	Right	Papillitis	4 days	Negative	Negative	20/200	Rt. mid. turb. and sphenoid	Normal	Pus and gran.	
9b.	Dr. F. H. Verhoeff..... (M. C. E. & E. I.)	Left	Papillitis	1 wk.	Negative	Negative	20/30	Left antrum	Normal	Pus	
10.	Dr. F. H. Verhoeff..... (M. C. E. & E. I.)	Right	Neuroretinitis and choroiditis	3 mos.	Negative	Negative	Nil	Rt. mid. turb., ethmoid and sphenoid	No improvement	Pus and gran.	Headaches relieved
11.	Dr. W. J. Daly.....	Left	Axial neuritis	8 mos.	Polypoid tissue	Erosion in sella turcica, etc.	20/200	None	Round cell sarcoma	Death from streptococcus meningitis
12.	Dr. F. E. Cheney.....	Left	Chronic optic neuritis	4 mos.	Def. septum; pus	Ethmoids and sphenoids hazy	14/20	Left mid. turb., post. ethmoids and sphenoid	16/20	Pus in sphenoid	
13.	Dr. P. H. Thompson... (M. C. E. & E. I.)	Both	Chronic optic neuritis	4 mos.	Def. septum; hyper. mid. turbs.	Negative	20/200	Both mid. turbs., post. ethmoids and sphenoids	20/100	Pus	
14.	Dr. F. M. Spalding..... (M. C. E. & E. I.)	Both	Neuroretinitis	4 wks.	Def. septum; hyper. mid. turbs.	Negative	Nil	Both mid. turbs. and post. ethmoids	Fingers 20 ft.	Pus	Child of 5 years
15.	Dr. Alex. Quackenboss (M. C. E. & E. I.)	Left	Papillitis	1 mo.	Hyper. left mid. turb. and pus	Ethmoids obscured	Lt. fingers 1 ft., Rt. 20/40	Left mid. turb., post. ethmoids and sphenoid	Lt. fingers 2 ft., Rt. 20/20	Pus in sphenoid under pressure	Question of malingering
16.	Dr. E. T. Easton.....	Right	Retrobulbar neuritis with some optic atrophy	2 yrs.	Def. septum; hyper. mid. turb.	Negative	20/200	Rt. mid. turb., post. ethmoid and sphenoid	20/100	Hyperplasia	Progress of optic atrophy checked
17.	Dr. Henry Hawkins....	Both	Papillitis	7 days	Hyper. mid. turb.	Negative	20/30 Rt. 20/100 Lt.	Left mid. turb., post. ethmoids and sphenoid	Normal	Hyperplasia	
18.	Dr. Alex. Quackenboss	Left	Acute retrobulbar neuritis	4 wks.	Def. septum; hyper. mid. turb.	Negative	20/100	Left mid. turb., post. ethmoids and sphenoid	Normal	Hyperplasia	Slight pallor of disk
19.	Dr. C. F. Worthen.....	Right	Acute optic neuritis	3 wks.	Marked hyper. mid. turb.	Negative	Fingers 3 ft.	Rt. mid. turb., post. ethmoids and sphenoid	20/70	Cystic mid. turb.	
20.	Dr. C. F. Worthen.....	Both	Chronic retrobulbar neuritis	4 mos.	Hypertrophic rhinitis	Negative	Rt. 20/100 Lt. 20/70	Local treatment	Nearly normal	Hyperplasia	
21.	Dr. P. H. Thompson... (M. C. E. & E. I.)	Both	Chronic retrobulbar neuritis	9 mos. left 3 mos. rt.	Hypertrophy, both mid. turbs.	Negative	Lt. fingers 4 ft., Rt. 20/70	Both mid. turbs., post. ethmoids and sphenoid	20/200 Rt. Fingers 4 ft. left	Hyperplasia	Atypical multiple sclerosis
22.	Dr. G. S. Derby..... (M. C. E. & E. I.)	Right	Acute retrobulbar neuritis	7 wks.	Hyper. mid. turb.	Negative	Nil	Rt. mid. turb., post. ethmoids and sphenoid	Unimproved	Hyperplasia	Optic atrophy
23.	Dr. Alex. Quackenboss (M. C. E. & E. I.)	Right	Acute retrobulbar neuritis	8 days	Def. septum; hyper. mid. turb.	Negative	Nil	Sept., mid. turb., post. ethmoids and sphenoid	20/20—	Hyperplasia	Slight pallor of disk
24.	Dr. S. J. McDonald.... (M. C. E. & E. I.)	Right	Acute retrobulbar neuritis with some optic atrophy	11 days	Hyper. mid. turb.	Negative	Nil	Rt. mid. turb., post. ethmoids and sphenoid	Fingers 6 inches	Membranous sac in ethmoids	Partial optic atrophy
25.	Dr. W. N. Souter..... (M. C. E. & E. I.)	Left	Acute retrobulbar neuritis	9 days	Hyper. mid. turb.	Negative	Light perception	Left mid. turb., post. ethmoids and sphenoid	Normal	Pus in ethmoid	

negative. Two days later the septum was resected, the right middle turbinate removed, and the right posterior ethmoids and sphenoid opened. The posterior ethmoid was unusually large, and located directly in front of the sphenoid, so that when opened at a depth of $3\frac{1}{2}$ inches it was mistaken for that sinus. A small opening, however, was discovered near the septum, which led into a cell one-half inch deep, which proved to be a rather small sphenoid. The vision did not improve as rapidly as usual, and on the patient's discharge at the end of a week, fingers could be distinguished only at 5 feet. A severe cold was contracted on the way home, and for a day the vision became nil. Under hot irrigations the patient gradually improved. In two months, vision was 20/20 —, with some pallor of the disk.

CASE 24.—Mrs. B. M. T., aged 40, referred by Dr. S. J. McDonald at the infirmary, Jan. 19, 1920, with a diagnosis of retrobulbar neuritis, right, of three days' duration, had complete loss of vision. The pupil did not react to light. The blood vessels were rather small, the disk, pale. The right middle turbinate was somewhat obstructive posteriorly. Examination otherwise was negative. The roentgen-ray, Wassermann, medical and neurologic examinations were negative. An immediate operation was advised, but the consent of the patient could not be obtained, so that it was not until January 27, eleven days after the onset of the trouble, that she permitted me to operate. The middle turbinate, which proved to be much larger than it appeared, was removed, and the posterior ethmoids and sphenoid opened. In one of the posterior ethmoids there was a thick membranous sac, mention of which has previously been made. The patient was discharged four days later, with vision unimproved. Ophthalmologic examination revealed: "No light perception; pupil reacted slightly to light; motion normal; very slight pain on pressure over eye; disk more hazy and indistinct than in other eye, and the physiologic cupping absent, with a higher color to disk; blood vessels about the same in the two eyes." Five weeks after operation, examination revealed a well developed optic atrophy. The patient was, however, able to see fingers at 6 inches. This case is one in which the patient would probably have been benefited had she consented to an earlier operation.

CASE 25.—Mrs. J. M. P., aged 27, referred by Dr. W. N. Souter at the infirmary, Jan. 26, 1920, with a diagnosis of retrobulbar neuritis, right, of six days' duration, had had a blurring in the same eye some months previously, which had cleared up without treatment. Following a slight cold, large objects seemed in a thick haze. In six days there was barely light perception. Dr. Derby examined the fundus and reported "outline of disk somewhat blurred. Not as much physiologic excavation in left eye; vessels about the same size; foggiest of disk and higher color. Vision, right, 20/20. Question of light perception, left." Physical, dental, neurologic, roentgen-ray and Wassermann tests were all negative. The nasal examination was practically negative except that the posterior portion of the left middle turbinate seemed somewhat enlarged. January 29, nine days after the onset of the trouble, the middle turbinate was removed and the posterior ethmoids and sphenoid were opened. A small amount of pus was found in one of the posterior ethmoids, and the tissue was somewhat thickened. In two days the patient could count fingers at 6 inches. Vision improved rapidly so that in two weeks it was 20/30, and at the end of a month was normal.

GENERAL SUMMARY

Of the twenty-five cases here reviewed, operation was not performed in three (Cases 1, 11 and 20). In the first, the eye remained permanently blind. In the second, the patient died from a sarcoma; and in the third, the vision was improving when first seen and recovered under local treatment. In a fourth (Case 3) a hypertrophied middle turbinate was removed some time after the vision had returned.

Of the twenty-two operative cases there was improvement in all but three (Cases 10, 21 and 22).

In one the eye had been practically blind some months. In another of five weeks' duration there was slight improvement at first, but pressure had continued so long that optic atrophy resulted. The third case was one of multiple sclerosis.

Normal vision was obtained in nine cases (Cases 2, 3, 5, 7, 8, 9, 17, 18 and 25).

There was marked improvement in four (Cases 6, 14, 19 and 23), but some optic atrophy.

There was only slight improvement in six (Cases 4, 12, 13, 15, 16 and 24), this being due to the chronic nature of the disease and the delay in operating.

In three there appeared to be a direct extension of the infection (Cases 11, 14 and 15).

The toxemia from pus found in eight cases seemed the chief factor (Cases 1, 4, 8, 9, 10, 12, 13 and 25).

Hyperplasia appeared the predominating lesion in fourteen (Cases 2, 3, 5, 6, 7, 16, 17, 18, 19, 20, 21, 22, 23 and 24).

In six, the nasal examination was considered negative (Cases 2, 4, 5, 7, 9 and 10).

In seven, roentgen-ray examination was positive (Cases 1, 2, 3, 4, 11, 12 and 15). Negative plates, let me add, by no means contraindicate an operation. This is especially so in hyperplasia, as only two of the fourteen cases showed any roentgen-ray findings.

The middle turbinate was removed in all the cases in which operation was performed, and the sphenoid opened in all but one (Case 3).

The posterior ethmoids are at present opened as a matter of routine. Unless suspected of infection, the other accessory sinuses are not disturbed. The complete ethmoid exenteration does not in most cases seem necessary.

The accompanying table summarizes the individual findings in the cases studied.

390 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. S. G. HIGGINS, Milwaukee: Be very sure of your diagnosis before you undertake an accessory sinus operation. I might possibly differ some with the essayist as to his technic in removing all of the middle turbinate, but something can still be learned as to the best technic in ethmoidal surgery. We have not the ideal operation as I understand it. We ought not to operate so frequently that the internist who refers our sinus cases has a larger series of negative results than he has positive results. As rhinologists we ought to require from the ophthalmologist a complete history which may aid us in making a diagnosis before we operate. If other things seem to be failing, operation is clearly indicated, and if you get a negative result it is to be hoped that no harm has been done.

DR. LEON E. WHITE, Boston: These cases were all rather extreme, and were referred by competent ophthalmologists after having been thoroughly investigated, as they felt that unless relief could be given at once, the eyes would be lost. I do not believe in operating on any patient that shows a tendency to improve; but it is very important to operate before it is too late. In the case I reported, of eleven days' duration, the woman declared there was nothing the matter with her nose. The eye men felt, as there were no other findings, that the trouble was probably in the accessory sinuses. There was a cyst in one of the posterior ethmoids and distinct pathologic conditions that were not evident on inspection. I want to emphasize the point that these cases cannot go too long, that we cannot waste too much time in investigating them. Dr. Stark made a good point in the discussion which he had prepared. In speaking of those cases which recover spontaneously, he said that when there

was a pressure sufficient to cause these symptoms there was probably some condition in the nose that needed attention; even though the patient recovers it is advisable to investigate thoroughly the condition, and if anything is found, it should be taken care of in order to prevent later complications, especially multiple sclerosis. An illustration of this occurred the day I left Boston.

NERVE BLOCKING FOR NASAL SURGERY *

ROBERT G. REAVES, M.D.

GREENSBORO, N. C.

My object in this article is to give a brief description of nerve blocking by procain, as used in twenty-nine nasal operations, with complete anesthesia in all except two cases.

In order to produce anesthesia in either nasal chamber, one needs to inject only two points; namely, the exit of the nasal nerve from the orbit, and the region of Meckel's ganglion. In view of this fact, it will be of advantage to give a brief review of the anatomy concerned, according to Gray:

Meckel's (sphenopalatine) ganglion is deeply placed in the sphenopalatine fossa, close to the sphenopalatine foramen . . . and is situated just below the superior maxillary nerve. . . . Its sensory root is derived from the superior maxillary nerve. . . . Its motor root is derived from the facial nerve through the large superficial petrosal nerve, and its sympathetic, from the carotid plexus through the large deep petrosal nerve. These two nerves join together to form a single nerve—the vidian.

Branches of Distribution of the Sphenopalatine Ganglion.—These are divisible into four groups: . . . ascending, which pass to the orbit; descending, to the palate; internal, to the nose; and posterior branches, to the nasopharynx. . . . The descending or palatine branches . . . are three in number, anterior, middle and posterior. The anterior palatine nerve . . . gives off inferior nasal branches, which enter the nose through openings in the palate bone and ramify over the turbinated bone and middle and inferior meatuses. . . . The internal branches are distributed to the septum and outer wall of the nasal fossae. They are the superior nasal and the nasopalatine. The superior nasal branches, four or five in number, enter the back part of the nasal fossa by the sphenopalatine foramen. They supply the mucous membrane covering the superior and middle turbinated processes, and that lining the posterior ethmoidal cells, a few being prolonged to the upper and back part of the septum. The nasopalatine nerve also enters the nasal fossa through the sphenopalatine foramen; it passes inward across the roof of the nose, below the orifice of the sphenoidal sinus, to reach the septum, and then runs obliquely downward and forward along the lower part of the septum, to the anterior palatine foramen, lying between the periosteum and mucous membrane. It descends to the roof of the mouth through the anterior palatine canal.

The nasal nerve enters the orbit by way of the sphenoidal fissure between the two heads of the external rectus, and passes obliquely inward across the optic nerve beneath the superior rectus and superior oblique muscles, to the inner wall of the orbit. Here it passes through the anterior ethmoidal foramen, and, entering the cavity of the cranium, traverses a shallow groove on the front of the cribriform plate of the ethmoid bone, and passes down through a slit by the side of the crista galli into the nose, where it divides into two branches, an internal and an external branch. The internal branch supplies the mucous membrane near the fore part of the septum of the nose. The external branch descends

in a groove on the inner surface of the nasal bone and supplies a few filaments to the mucous membrane covering the fore part of the outer wall of the nares as far as the inferior turbinate process; it then leaves the cavity of the nose, between the lower border of the nasal bone and the upper lateral cartilage of the nose, and, passing down beneath the compressor nasi, supplies the integument of the ala and the tip of the nose, joining the facial nerve.

PROCEDURE OF INJECTIONS

A. *Nasal Nerve.*—1. Instil a few drops of 4 per cent. cocain into the conjunctival sac to prevent pain on inserting the needle.

2. Lift the upper lid upward and inward by placing the thumb at the inner and upper margin of the orbit and direct the patient to look outward. Insert the needle through the plica semilunaris just below the upper lacrimal puncta, directing it slightly inward and upward, at an angle of about 30 degrees. The needle will soon strike the os planum, and on moving the point of the needle up and down, when inserted about 2 cm. ($\frac{3}{4}$ inch) in depth; it will engage in a groove the anterior end of which terminates in the anterior ethmoidal foramen. Here the nasal nerve leaves the orbit. Inject about 1 c.c. of 1 per cent. solution of procain.

B. *Meckel's Ganglion.*—1. Brush the hard palate with a solution of cocain along the root of the molars.

2. Place the index finger on the hamular process of the internal pterygoid plate and bring it forward until a depression, the lower end of the posterior palatine canal, is palpated.

3. Place the needle at an angle of about 45 degrees with the upper teeth and along the second molar about $\frac{1}{8}$ inch from its root. This brings the needle near the canal, which it usually enters after three or four attempts. Pass the needle upward about 2.75 to 3.5 cm. (1 to $1\frac{1}{4}$ inches), when the point will be near Meckel's ganglion. Inject from 1 to 1.5 c.c. of 1 per cent. solution of procain.

The injection of the nasal nerve is a very easy procedure. One can readily tell by careful manipulation when the needle is engaged in the groove near the anterior ethmoidal foramen. The injection of the Meckel's ganglion is a little more difficult, as one has to locate the canal, but usually this is not hard to do. If the needle be placed a little too far back, it may pierce the soft palate, in which case the fluid may run down the nasopharynx. If it be placed forward, it may puncture a vessel on the hard palate and cause a little bleeding. The second molar is an excellent guide for the site of injection, if one remembers that the canal is close to the margin of the hard palate. I had considerable difficulty in one case, as I took the first for the second molar. The patient finally remarked: "My wisdom tooth was pulled." From this information I soon located the canal.

Force was not used in passing the needle through the canal, as the needle passes rather easily when properly manipulated.

The Luer's glass syringe (1.5 c.c.) was used and found very satisfactory. Straight needles $1\frac{1}{2}$ inches long, ranging in gage from 23 to 25, are very satisfactory for injecting Meckel's ganglion. They should be of good quality, and have neither a sharp nor blunt end, but rather a bevel point. A bevel point is easily obtained by filing off the sharp end of the ordinary needles. Any small needle about 1 inch long does well for the injecting of the nasal nerve.

* Read before the Section on Laryngology, Otology and Rhinology at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

The following objections have been considered in regard to the foregoing injections: (a) Danger of carrying infection into the orbit. (b) Puncture of the roof of the orbit by undue force. (c) Injury to blood vessels in the posterior palatine canal. (d) Carrying infection into the region of Meckel's ganglion.

So far none of these objections have been encountered. Normally the conjunctival sac contains very few bacteria. If deemed advisable, one may use 4 per cent. protargol, as an antiseptic for the conjunctival sac. One could puncture the roof of the orbit with the needle, but such force is to be considered poor manipulation on the part of the operator. Chances of injuring the vessels in the posterior palatine canal seem small, as the needle with a bevel point is being passed parallel to the vessels. Even if the fluid is injected directly into the vessel, the amount is not sufficient to give any alarming toxic symptoms. If one is afraid of infection, alcohol may be rubbed over the site of injection.

Four of the patients had a little edema and discoloration of eyelids, which passed off in a day or so. A few had paralysis of the internal rectus, which passed off after the effect of the procain wore off.

Sterile solutions of procain, varying in strength from 1 per cent. to 2 per cent., were used. One per cent. gave good anesthesia within about five minutes, and lasted thirty minutes or longer. Less than 2 grains were used in all but one case, in which 4 grains were used. In the majority of cases "Novocain and L-Suprarenin Tablets 'A,'" made by Farbwerke-Hoechst Company, New York, were used. Each tablet contains novocain 0.125 gm., and l-suprarenin, 0.000125 gm. (which equals about 2 minims of 1:1,000 epinephrin). L-suprarenin is a synthetic preparation made by the above named firm. In other cases, procain to which sterile epinephrin was added in proportion of from 6 to 10 minims to 10 c.c. of 1 per cent. solution was used. When epinephrin was added to procain the two were mixed (usually in the syringe) in the foregoing proportion, and injected almost immediately. If mixed and allowed to stand for a while, the procain loses a large part of its anesthetic power. At first no precaution was taken as to whether the physiologic sodium chlorid solution, the solvent, was alkaline or acid. After failing to get proper anesthesia in two cases, I wrote the company which made the tablets "A" and was informed by them that if the solvent was alkaline, it would destroy the anesthetic property of the procain. After this the solvent was tested to be sure it was neutral or only slightly acid, and there was no more trouble in getting proper anesthesia. In order to obtain as little bleeding as possible, it is advisable to pack the nasal chamber with about equal parts of 5 per cent. cocain and epinephrin.

A semiupright position was used for the patients, and was found excellent both for the patient and the operator. It relaxes the patient and enables him to be comfortable. This position is objected to by some operators, but there is only one answer and that is: "I must see the field of operation before I operate in the posterior ethmoidal region."

Twenty-two of the twenty-nine operations were performed at the Massachusetts Charitable Eye and Ear Infirmary, Boston, during the summer and fall of 1917. They were of all varieties—ethmoid, sphenoid, intranasal frontal, intranasal antrum, submucous resection and turbinectomy. I was more impressed

with the anesthesia for sinus than for septal work, as good anesthesia of the septum is obtained by packing. The war interfered with this work, and very little has been done since 1917.

This article is offered more as a preliminary report, rather than a report of work completed. I hope to make a report later on, as to just which part of the nose is anesthetized by injecting Meckel's ganglion, and which part by injecting the nasal nerve separately.

ABSTRACT OF DISCUSSION

DR. H. H. MARTIN, Savannah, Ga.: Some time ago when Sluder first advocated the injection of Meckel's ganglion, I was visiting with Dr. Reaves and his brother, and they had for a year or more been injecting Meckel's ganglion through the posterior palatine canal. It is easily as effective as injecting through the nose, but in my hands it has not been done so easily. I prefer the Sluder method, that is, a long needle inserted through the posterior end of the middle turbinate, getting it in the right position, and giving it a slight tap with a hammer. Dr. Reaves' idea of injecting the exit of the nasal nerve is entirely new to me. I had not heard of it before, but in his hands it certainly seems perfectly practical. I do not see why it should not be used in a great many cases. Personally, however, I do not believe in injecting local anesthetics when you can apply them topically. The topical application is much safer, as a rule. However, a weak solution of procain injected into Meckel's ganglion will certainly produce an anesthesia of every ramification of that organ. Many men with whom I have been in correspondence inject the ganglion first, and then by placing a cotton pledget covered with cocain paste high up between the septum and the lateral wall of the nose anesthesia is produced. Sluder applies a strong solution of cocain directly over the sphenopalatine foramen.

DR. ROBERT G. REAVES, Greensboro, N. C.: This is simply my observation. In regard to the Sluder method, I have only tried it a few times, but I never was certain whether I was going into the cranial cavity or not. I was afraid. This way, with a needle one and one half-inches long, you would have to have a very small patient before you got into the cranial cavity.

EFFECTS PRODUCED ON BLOOD PICTURE BY OXYGEN INFLATION OF PERITONEAL CAVITY*

CHARLES GOODMAN, M.D.

Clinical Professor of Surgery, University and Bellevue Hospital Medical College; Surgeon, Beth Israel and Montefiore Hospitals

NEW YORK

Our attention has been directed of late to roentgenograms of the abdominal organs in which the outlines were brought out by the use of oxygen inflation of the peritoneum. Last fall I decided to make use of this technic, and began by making several peritoneal inflations in my service at the Beth Israel Hospital. Credit for the original idea of the use of oxygen as an aid in roentgen-ray diagnosis of the abdomen must be given to Kelling. His views were published in 1902. The method received little or scant attention until Jacobaeus took it up eight years later, and he was followed by several others. Stewart and Stein again discussed the procedure. They state that if the peritoneum is distended with oxygen, the gas will be absorbed within twenty-four hours. This is contrary to my observations. Dr. Charles Gottlieb and I have

* Read before the Eastern Medical Society of New York, March 12, 1920.

observed that, while much of the gas may be absorbed within twenty-four hours, the presence of some of it can be demonstrated with the roentgen ray for two weeks after the injection. Before introducing the oxygen into the peritoneal cavity, I decided to observe what effect 1,000 or 2,000 c.c. of oxygen would produce on the blood picture of the subject when introduced into the closed cavity of the peritoneum. I had observed in five patients at the Beth Israel Hospital in whom the peritoneal cavities were inflated with 1 or 2 liters of oxygen that the number of erythrocytes was increased from 80,000 to several hundred thousand after the oxygen inflation. The oxygen was introduced into the peritoneal cavity through a cannula passed through the abdominal wall. I found that the injection of more than 1 or 2 liters caused unnecessary discomfort to the patient. Our first case was a postoperative empyema.

TABLE 1.—RESULTS OF INFLATIONS

Cases	Red Blood Cells		Net Increase in Red Blood Cells
	Before Injection of Oxygen	24 Hours After Inflation	
1. Postoperative empyema.....	4,000,000	4,080,000	80,000
2. Tumor of kidney.....	3,900,000	4,800,000	840,000
3. Suspected ulcer of stomach.....	4,000,000	5,600,000	1,600,000
4. Subphrenic abscess.....	3,680,000	4,160,000	480,000
5. Pelvic tumor.....	5,730,000	6,260,000	530,000

RESULTS OF FURTHER INVESTIGATIONS

As the results were so gratifying, I followed these observations with similar ones on some of the chronic invalids of the Montefiore Hospital. About 1,000 c.c. of oxygen were injected into the peritoneal cavity in two cases of splenomegaly and in a case of inoperable carcinoma of the stomach. The two cases of splenomegaly gave positive Wassermann reaction. The results of these inflations are shown in Table 2.

TABLE 2.—RESULTS OF INFLATIONS IN CHRONIC INVALIDS

Cases	Red Blood Cells		Net Increase in Red Blood Cells
	Before Injection of Oxygen	24 Hours After Inflation	
1. Splenomegaly.....	3,920,000	6,200,000	2,280,000
2. Splenomegaly.....	4,400,000	6,000,000	1,600,000
3. Inoperable carcinoma.....	6,280,000	6,600,000	320,000

EFFECT IN PERNICIOUS ANEMIA

We also observed results in a case of the fatal form of pernicious anemia. The patient's red blood cell count was only 480,000, and the count made twenty-four hours after the peritoneal cavity had been inflated showed a net increase of 1,680,000, or a total of 2,160,000. I have not been able to find similar reports by others.

POSSIBLE MECHANICAL EFFECT

I believe that the results of our observations may be due to the mechanical effect of the pressure of the gas on the larger abdominal venous trunks. Some support to this contention is given by the results obtained several weeks ago by Dr. Max Kahn, who performed some animal experiments for me in the laboratory of the Beth Israel Hospital. Pneumoperitoneum produced in six rabbits inflated with oxygen showed in each of the six rabbits injected a net increase of from 200,000 to 900,000 red blood cells. He then inflated the peritoneal cavity of three rabbits with nitrogen gas, and the results were similar. The blood taken from these

rabbits showed an increase in the red blood cell count of 200,000, 300,000 and 500,000, respectively.

THERAPEUTIC SIGNIFICANCE

I am not prepared at this time to make any statement as to the value of this procedure as a therapeutic measure. I have no direct evidence that oxygen introduced into the closed peritoneal cavity has any direct stimulating effect on the hematopoietic organs and therefore I am not prepared to suggest that the method might be utilized in the treatment of anemia. On the other hand, my observations lead me to believe that the gas acts as a splint by giving support and pressure to the larger venous trunks of the abdomen and thus might be utilized in the treatment of shock.

CONCLUSION

As far as I have gone, I have concluded that oxygen injected into the peritoneal cavity is followed by an appreciable increase in the number of red blood cells in the peripheral circulation, which is demonstrated by the blood count. Further experiments will be undertaken with a view to determine definitely the value of this measure.

New Instruments**

BILATERAL EMPYEMA; STAPHYLOCOCCUS PYEMIA *

ROGER DURHAM, M.D., BROOKLYN

Surgeon, Greenpoint and Kings Park Hospitals, Assistant Surgeon, Methodist Episcopal Hospital

This rather unusual case presents many interesting and difficult problems arising in the course of an infection. Beginning as influenza, the infection ran a most profoundly severe and toxic course because of the presence of *Staphylococcus aureus* involving both middle ears, both parotid glands, both lungs, both pleurae and numerous other points of infection, and it terminated with a destructive inflammation of the crest of the right ilium. The disease processes encountered were influenza, bilateral otitis media, mastoiditis, bilateral septic parotitis, bilateral bronchopneumonia, bilateral pleurisy, bilateral empyema, pyemia, pressure necrosis, trophic neuritis, and osteomyelitis of the ilium. The patient, though recovery was many times despaired of, safely weathered these attacks for a period of six months or more, the heart never failing, the renal organs remaining undamaged, the gastrointestinal tract continuing to function, and final recovery being attained.

REPORT OF CASE

A boy, aged 14 years, became sick, March 1, 1919, and was referred to me by Dr. Hartwig Kandt, who directed the medical treatment of the case. The only facts pertinent to the disease are those of his present illness. The onset was sudden, with general body pains, chilly sensations, congestion of the nasopharynx, and prostration, pointing to the diagnosis of influenza. At the outset the type of toxemia was seen to be most severe, with a temperature range up to 105, pulse rate up to 140, and respirations of between 35 and 50. Blood pressure was subnormal, with a systolic reading of 100, and diastolic of from 50 to 60. Cough was present with mucus expectoration, several early attacks of epistaxis, sharp pain in the left chest, and increasing delirium.

The organism responsible for the sequence of pathologic conditions that followed was *Staphylococcus aureus*, and on the fifth day of the disease it was recovered from the sputum.

* Read before the Medical Society of the County of Kings, Jan. 20, 1920.

in great preponderance. The leukocyte count was low, being 7,400, with 70 per cent. polymorphonuclears; the urine was normal except for a trace of albumin. On the eighth day a slight discharge was noted from the right ear, and both drums were later incised, the culture from the discharge showing in each case *Staphylococcus aureus*. Four days later a swelling was noted over the right parotid, which was painful, tender and red. Meanwhile signs of consolidation of the left lung had developed, and the condition of the patient was that of a tremendously severe type of toxemia. The following day the opposite parotid became tender and swollen, and an area of infection was noted on the outer aspect of the left arm. Delirium was constant, the patient was restless and talkative, urination was frequent and incontinent, and both ears discharged profusely.

On the sixteenth day of the disease, aspiration of the left chest gave 30 ounces of a clear serum, culture from which showed *Staphylococcus aureus*. The right parotid was also incised at this time, revealing a burrowing infection of the gland with extensive necrosis, the same organism being recovered in the culture. Next day the left parotid was incised, and a similar condition found, due to the same organism. On the eighteenth day the infection of the left arm was likewise opened and the same organism recovered. Blood cultures taken at this time and a week later were, however, sterile. The white cell count had increased to 44,000 and the polymorphonuclears to 92 per cent.

During this period, the second and third weeks of the disease, the condition of the patient continued to be most critical, with a temperature range of 102 to 104, a pulse rate of 110 to 120, respirations of 30 to 40, active delirium, involuntary urination, etc. But the intake of fluid was ample, the urine output being 45 or more ounces a day, with no evidence of a failing heart, and blood pressure near the normal.

On the twenty-fourth day, fluid aspirated from the left chest had the appearance of creamy pus, and the patient was removed to the hospital for the necessary thoracotomy. Under 2 per cent. procain, 2 inches of the left ninth rib, in the posterior axillary line, were resected, 16 ounces of pus evacuated, and drainage maintained by means of two large rubber tubes. The parotids, still discharging from several pockets, were more widely incised, and Dakin's tubes inserted. Hemanalysis revealed 4,496,000 red cells, 75 per cent. hemoglobin, 25,000 leukocytes, and 69 per cent. polymorphonuclears. The Wassermann test was negative, and the spinal fluid presented a normal count and sterile culture. The reaction to this operative procedure was not alarming, the primary rise of temperature to 105 and over being followed on the third day by a general fall to between 101 and 102, with no improvement in the mental condition, etc.

About this time the opposite lung became involved, progressing to complete consolidation of the entire lower lobe by the thirty-fourth day of the disease, accompanied by embarrassed respirations of from 60 to 70; but the patient's mind was clearer. The blood picture was less favorable, because of rather rapid type of hemolysis, showing 3,216,000 red cells, and 55 per cent. hemoglobin on the thirty-first day, and 2,936,000 red cells and 50 per cent. hemoglobin two days later. The increasing anemia was plainly apparent to the eye, all the wounds appearing pale and sluggish with profuse discharges, and showing a tendency to spread. Moreover, three areas of pressure necrosis had developed over the sacrum and the posterior spines of the ilium, as well as a spot of dry gangrene on the glans penis. The mastoid processes were very tender, and the overlying skin edematous. It was quite evident that the patient was losing ground, and the outlook appeared gloomy.

He had begun to yield to the added infection due to the involvement of the opposite lung, and the progressing pyemia. At this critical moment resort was had to blood transfusion, 1,010 c.c. being given after the Miller method. Next day the red cell count had jumped to 4,450,000, and the hemoglobin to 68 per cent., and with this the mind was clearer, the skin pink, the heart sounds good, the lungs unchanged. The change in the appearance of all the wounds was most noticeable, showing active, pink and healthy granulations, and a marked lessening of the discharge.

Flatness of the right lower lobe persisted, and on the thirty-seventh day 1,050 c.c. of cloudy fluid were withdrawn, culture from which yielded the staphylococcus. Favorable signs were the nearly healed parotid wounds, the improved condition of all bed sores, and a clearer condition of the mind.

The problem now was the procedure to be adopted for the treatment of the second empyema, in the presence of the opposite unexpanded lung with its unhealed thoracotomy wound. The dangers of a second thoracotomy at this time were obviously too great to be undertaken. The use of a suction apparatus, such as the Phillips, was out of the question, because of the other surgical conditions present, and also the unreliability that it had shown in my experience with it. Therefore, to maintain the capacity of the new cavity at a minimum and prevent lung compression, and at the same time to evacuate the pus accumulation and allow for the formation of lung adhesions, repeated and frequent aspirations of the pleural cavity were resorted to, by means of a Chapman water pump attached to a nearby faucet. In this way from 75 to 175 c.c. of pus were aspirated at intervals of from two to four days. During these days three more abscesses were incised and the staphylococcus recovered each time. Also an area of dry gangrene appeared over the left heel, and foot drop due to trophic neuritis was noted.

An effort to sterilize the fluid in the right chest was made by the use of 2 per cent. solution of formaldehyd in glycerin injected into the cavity after each aspiration; but the only result apparent was a change in the character of the discharge from a thick pus to a thin, reddish fluid. The culture still showed the causative organism.

Meanwhile the ear drums healed, the mastoids had cleared, and the parotids were nearly well. The management of the condition was maintained as described for more than three weeks, and some improvement was manifest in the general condition of the patient; but about the sixtieth day of disease a downward trend was noted. The patient was more irrational, having restless nights, and taking less nourishment. The temperature assumed the septic type. The cavity of the left chest measured at this time only 6 ounces. The red cell count showed a fall of one-third million, and the hemoglobin dropped from 78 to 65 and down to 60 per cent. in a few days. The leukocytes increased from 22,000 to 38,000, and the red cell count was slightly above 3,000,000. The temperature showed a sharp afternoon rise to 103, and the pulse and respiratory rates revealed an upward trend. A further abscess of the left sacral region was opened and the staphylococcus obtained.

It now became apparent that improvement had ceased in the general condition of the patient, and, on the contrary, there was a general retrogression, accompanied by a rather rapid degree of hemolysis. Further delay in undertaking the second thoracotomy seemed inadvisable, and on the sixty-sixth day of disease, following a blood transfusion of 436 c.c., the eighth right rib was resected, and about 200 c.c. of pus evacuated. This cavity was treated after the third day by the Dakin technic (as had been done in the case of the opposite chest). There was practically no unfavorable reaction to this procedure, and improvement promptly began. During the period of the following ten days the temperature, pulse and respiratory rate decreased measurably, the red blood cells increased one-half million, the leukocytosis decreased, the mind became clear at all times, and the patient began to evidence interest in events.

Progress continued favorable, the left chest healing on the one hundred and tenth day and the right on the one hundred and eighteenth, and the patient returned to his home on the one hundred and twenty-ninth day of his disease, where the rate of progress was maintained, and all wounds went on to complete healing.

At this time, four and one-half months from the onset, complaint was made of pain and tenderness over the crest of the right ilium, and all evidences of a localized osteomyelitis appeared. The patient was again removed to the hospital, and about 3 inches of the crest of the ilium to a depth of one-half inch was found to be necrosed, and was excised. The recovery from this operation was prompt. All

the wounds had healed by seven and one-half months, the foot drop had practically cleared, and the patient was restored to complete health.

322 Park Place.

AN APPARATUS FOR THE USE OF ETHYL CHLORID WITH OTHER AGENTS

A. F. ERDMANN, M.D., BROOKLYN

Lecturer on Anesthesia, Long Island College Hospital

In 1903, Hewitt¹ suggested that ethyl chlorid might be combined with nitrous oxid gas for surgical anesthesia. He states that this combination is useful only for induction or for very short periods. His method of employment was somewhat uncomfortable, for it necessitated the use of one hand to manipulate or hold the container. He recognized the value of the method, and his reasons are as good now as then, and his success can be easily duplicated.

The apparatus herewith illustrated obviates all the older difficulties, and because of its other parts makes it feasible to use ethyl chlorid with, before or after another anesthetic, or alone as the anesthesiologist chooses. Those who are familiar with the original apparatus will quickly notice that the change consists merely in providing an attachment to hold the Gebauer tube on the handle, and in utilizing the opening intended for the manometer to receive the tube from the ethyl chlorid container. Furthermore, one is now enabled to exhibit any number of combinations of agents by simply using a double reservoir tube holding both ether and chloroform; or the quadruple form, adding anesthetic and any other agent desired.

I am enjoying my modification particularly in the case of patients the contour of whose face makes it difficult to apply a mask air-tight; in nose and throat operations and in gas-oxygen anesthetics when I would otherwise use "a little ether," and in that type of patients who do not quickly succumb to gas alone. I would suggest its availability, however, not only for the short case to which Hewitt limited himself, but also for any length of time and for any operation.

458 Ninth Street.

DOUBLE TUBAL PREGNANCY: ONE TWINS •

J. H. CARSTENS, M.D., DETROIT

Tubal pregnancy is not so rare as it formerly was supposed to be, but double tubal pregnancy is quite rare, and comparatively few cases have been recorded. Quite a few cases have been reported of a simultaneous tubal and normal pregnancy. Having had a case of a double tubal pregnancy, and one of these twins, I certainly thought that it ought to

be put on record, as I have not been able to find a report of any case in a hasty glance through the literature.

REPORT OF CASE

Mrs. W. N., aged 23, married seven months, with a good family history, and no sickness herself except some of the diseases of childhood, had always menstruated regularly, with slight spasmodic pain. The last normal menstruation occurred, Oct. 25, 1919. November 23, she had some pains, cramps as she called them, and a slight showing. These continued, sometimes quite severe for an hour or two, and then not noticeable for the balance of the day. She consulted me to find out whether or not she was pregnant. She was a healthy looking woman, with a nice pink complexion. On examination, I could map out the uterus easily, apparently slightly enlarged, with soft cervix. To the right was a well marked swelling, not hard or fluctuating. On the left side, I could not detect anything abnormal.

This was evidently an extra-uterine pregnancy, and I urged a prompt operation; but it took several days before I could get her to the hospital. December 5, I operated, and found the uterus in the normal place, and the right tube enlarged very much and empty, so that the thumb could easily enter to the junction with the uterus. The culdesac was a mass of blood, coagulated and of various colors, showing that it had been deposited there on various days. There was comparatively little: I should say 3 or 4 ounces. No attention was paid to it then. The tube was removed, but an effort was made to keep it patulous by sewing the mucous membrane to the serous covering. The culdesac was now carefully cleansed. On looking at the left side, I found the tube absolutely closed, very dark and about 2½ inches long, and 1½ inches in diameter, evidently another tubal pregnancy. This was carefully removed, and also an effort made to keep the tube patulous by stitching the mucous membrane to the serous covering at the horn of the uterus. The abdomen was closed with plain sterilized catgut, and the woman made an uneventful recovery.

On opening up the left tube, we found two small fetuses about three-fourths inch long. I should judge that the right tube must have been a pregnancy of six weeks, and the left one, containing the two, of about three weeks.

NITROBENZENE POISONING WITH CYANOSIS

REPORT OF CASE

FRANK G. SANDERS, M.D., FORT WORTH, TEXAS

Several cases of methemoglobinemia due to some poisonous substance in shoe dye have been reported in the literature recently.¹ In the cases occurring at Camp Joseph E. Johnson and Camp Jackson, the cyanosis and symptoms of poisoning were found to be due to nitrobenzene, a constituent of the shoe dye used. In the former camp the cases occurred among recently commissioned officers who had had their puttees and shoes dyed and had worn them immediately. Recovery in these cases was prompt, taking place generally within twenty-four hours.

On the evening of Feb. 7, 1920, at about 6:30, a well dressed young man was brought into the Johnson and Beall Hospital. He was a railroad employee and had been in excellent health until the present afternoon. He had spent the afternoon at the theater and had gone to the interurban station to take the 6 o'clock car. The last thing he remembered was looking at his watch and noting that it was 3 minutes to 6. The person who brought him in stated that he had driven up to the mail box about 6 o'clock and had found the patient leaning over the package box apparently unconscious. He had brought the man directly to the hospital.

The patient was of good physique. He was conscious, but seemed confused, and said that he was dizzy and that his chest was full of something. He was markedly cyanosed

Apparatus for ethyl chlorid with other agents.

1. Hewitt, F. W.: Tr. Brit. Dental Assn., 1903.

* Read before the Detroit Surgical Society, April 9, 1920.

1. Stifel, R. E.: Methemoglobinemia Due to Poison by Shoe Dye, J. A. M. A. 72: 395 (Feb. 8) 1919; Report of a Case of Cyanosis at Camp Jackson, S. C., Due to Poisoning from Shoe Dye, *ibid.* 72: 592 (Feb. 22) 1919.

and gave the appearance of being intoxicated. The skin was cool and moist, the temperature normal. The heart and lungs were negative, as was the abdomen. During the examination a very decided odor of nitrobenzene became apparent, and this odor was traced to his shoes. Further questioning revealed the fact that the patient had had his shoes dyed immediately before going to the theater, and that he had sat in that poorly ventilated place all the afternoon breathing the fumes from his shoes. The shoes were very tight also, and direct absorption might have been a factor. The patient denied having a drink of any kind or any unusual food.

The man's shoes were removed and he was placed by the open window. Within an hour he was able to go home, with some assistance. He was advised to keep his shoes away from him and to stay by the open window. By the evening of the next day, his cyanosis had disappeared along with the subjective symptoms, and the patient was able to return to his work apparently none the worse for his experience.

GANGRENE OF LEG FROM THROMBOSIS OF POPLITEAL ARTERY FOLLOWING CORRECTION OF DEFORMITY *

JOHN JOSEPH NUTT, M.D., NEW YORK

This case is reported as bearing on the danger to which the popliteal vessels are exposed by forcible correction of deformities at the knee. Calot speaks of such an accident as "scarcely conceivable in spite of what is said in certain books. I have never observed it in my practice." Tubby says: "Others prefer sudden or complete reduction, although it must not be forgotten that such a procedure is accompanied by grave risks; these are rupture of the popliteal artery, which has occurred . . ."

REPORT OF CASE

W. B., aged 8 years, admitted to the State Hospital for Crippled and Deformed Children, Aug. 27, 1919, with a diagnosis of tuberculous disease of the knee, which had not been normal since the child was 2 years of age. Twice, for indefinite periods, the child had been in hospitals and some sort of operation had been done, as scars were present on the posterior surface. From the indefinite history, I assume that these operations were simply opening of abscesses. Discharging sinuses were said to have been present at different times.

The right knee was flexed, the thigh and leg much atrophied; the patient walked with a crutch, bearing no weight on the leg; there was no redness and no heat, the joint being immovable and in flexion of 135 degrees. Roentgenograms revealed that there had been an extensive rarefying osteitis, especially of the tuberosities of the tibia, followed apparently by a laying down of lime salts. The diagnosis from the examination was: arrested tuberculous disease of the knee.

September 14, the patient was placed under an anesthetic. Attempts made to straighten the knee were futile, no movement being possible. The knee was then opened and a resection performed. The tibia showed marked signs of previous activity of the infection, but fairly healthy bone was easily reached. The slice from the condyles exposed normal bone. Reduction of deformity was now accomplished but not without considerable force to overcome resistance in the posterior tissues. Plaster of Paris was applied from the toes to the groin. There was no complaint from the patient nor any signs of temperature until the sixth day, when the temperature shot up to 104, the pulse became correspondingly rapid, and discoloration of the toes appeared. Circulation in the toes had been examined twice daily and found to be excellent each time, so there is no question that it did not appear until the sixth day. The plaster of Paris was immediately removed, but gangrene extended up the leg and soon reached the junction of the upper and middle third, where it seemed to be arrested. The condition of the patient was so markedly septic that amputation was decided on.

October 1, this was performed at the junction of the middle and lower third of the femur. The femoral artery did not bleed and was found to be plugged. This part of the thrombus extended about one-half inch upward from the point of division. The recovery of the patient was satisfactory in every way. Careful dissection of the popliteal artery with slides of sections, by Dr. Alexander Frazer, showed the existence of the thrombus originating at the beginning of the posterior tibial artery and extending upward, as pointed out above, to the point of amputation. Dr. Fraser considers it without doubt thrombus of septic origin, and not traumatic. As the wound, from the day of resection, at no time showed signs of infection, I believe the infection must have arisen from an old nidus, which was aroused to activity by the traumatism at the time of operation. If this is correct, we may consider this case an evidence of the danger of forcibly overcoming a deformity when scar tissue is present; but it should not be considered as one of thrombosis arising from a traumatic injury to the vessel's walls from the correction of the deformity.

853 Seventh Avenue.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

STREPTOCOCCUS VACCINE (See New and Nonofficial Remedies, 1920, p. 290).

Gilliland Laboratories, Ambler, Pa.

Streptococcus Vaccine.—Made from hemolytic streptococci, 50 per cent., viridans (green-producing) streptococci, 40 per cent., and non-hemolytic streptococci, 10 per cent. (a number of strains of each type are included), and suspended in physiological solution of sodium chloride; three cresols, 0.25 per cent. is used as a preservative. Marketed in packages of four syringes containing, respectively, 125, 250, 500 and 1,000 million killed bacteria; in packages of four 1 Cc. ampules containing, respectively, 125, 250, 500 and 1,000 million killed bacteria; also in vials of 5, 10 or 20 Cc. containing 1,000 million killed streptococci per Cc.

Dichloramine-T-Abbott (See New and Nonofficial Remedies, 1920, p. 139).

The following dosage form has been accepted:

Tablets Dichloramine-T-Abbott, 4.6 grains.—Each tablet contains dichloramine-T-Abbott 4.6 grains.

SOLUTION ARSPHENAMINE-LOWY.—An aqueous 0.5 per cent. solution of arspenamine, possessing the proper degree of alkalinity.

Actions and Uses.—The same as those of arspenamine (see New and Nonofficial Remedies, 1920, p. 36).

Dosage.—Solution Arspenamine-Lowy is supplied in ampules of 80 c.c. and 120 c.c. These ampules should not be used after the date stamped on the label of each package or if the degree of coloration of the solution is greater than that of a control tube which accompanies the package.

Prepared by the Lowy Laboratory, Inc., Newark, N. J. U. S. patent and trademark applied for. Licensed for interstate sale by the U. S. Treasury Department under the "act to regulate the sale of viruses, serums, toxins and analogous products" as conforming to the regulations for the control, sale and manufacture of arspenamine, issued June 30, 1919.

Ampules Solution Arspenamine-Lowy 80 Cc.—Each ampule contains solution arspenamine-Lowy 80 Cc. (representing arspenamine 0.4 Gm.): a sterile needle for intravenous injection and sterile rubber tubing are supplied with each ampule.

Ampules Solution Arspenamine-Lowy 120 Cc.—Each ampule contains solution arspenamine-Lowy 120 Cc. (representing arspenamine 0.6 Gm.): a sterile needle for intravenous injection and sterile rubber tubing are supplied with each ampule.

Solution Arspenamine-Lowy is prepared by dissolving arspenamine (using the particular brand desired by the purchaser) in fresh, distilled water, carefully neutralizing with sodium hydroxide solution and sealing in ampules under a partial vacuum, the concentration being adjusted so that 100 Cc. of solution represents 0.5 Gm. of arspenamine.

Solution Arspenamine-Lowy is a clear yellow liquid which, depending on the brand of arspenamine used, varies from a canary yellow to a greenish yellow.

PELLAGRA

The etiology of pellagra has attracted the consideration of a number of investigators who have been able to study it on an unusually large scale and with exceptional facilities. In this country the zeist theory, which related pellagra in some way to the dietary use of maize and maize products, has been finally abandoned. An exclusive diet of corn is unquestionably inadequate; and corn damaged by microbiotic changes may well be harmful at times to persons ingesting it. But no adequate review of the actual incidence of pellagra, as it has occurred in different places and among different peoples, will any longer justify the assumption that the pathogenesis of the disease is concerned primarily with a corn factor. Pellagra may occur without the use of corn.

Epidemiologic studies showing peculiar localized occurrences of pellagra have fostered the natural conclusion that infection takes a part in its appearance. In a noteworthy contribution published in 1914, Goldberger¹ of the U. S. Public Health Service presented striking facts antagonistic to the theory of a pellagra infection but favorable to the long alleged relationship between diet and the disease. He pointed out that in some institutions, among the inmates of which pellagra was either epidemic or had long been endemic, the nurses and attendants, drawn from the class economically identical with that most affected in the population at large, appeared uniformly to be immune, although living in the same environment and under the same conditions as did the inmates, and many of them also in frequent and intimate contact with cases of the disease. Neither contact nor insect transmission seemed capable of explaining this remarkable exemption of one of the two classes of residents. The suggestion was made that the explanation was to be found in a difference in the diet of the two groups; for it was observed that although the nurses and attendants appeared to receive exactly the same food as did the inmates, there was, nevertheless, a difference in the diet of the two groups, in that the nurses and

attendants, being in a favorable position to choose from what was provided, selected the best for themselves. They were also free to supplement the institution diet in any manner they pleased.

Since 1914, the study of the pellagra problem has been vigorously prosecuted by the U. S. Public Health Service. The continued investigations conducted by Goldberger and his co-workers² have not altered the original suggestion that pellagra can be eliminated by attention to the dietary factor. The trend of the latest evidence³ is to show that basically the diets of the nonpellagrous and of the pellagrous households (of comparable economic status) in the communities and at the season studied are much the same, the only outstanding difference being a more liberal supply of the foods of the animal protein group in the diet of the nonpellagrous households. The difference between these diets seems to be one of degree, not of kind.

In practical experience, then, the preventive value of milk and of fresh meat seems to have been demonstrated. We are now assured by the latest government report that the total fuel supply—the calories of the diet—is not an essential factor in the production of pellagra. It is admitted that the total intake of protein in pellagrous households is apparently somewhat smaller than is the case in the nonpellagrous homes, but the minimum of safety is not believed to be reached in the region investigated. There is no overconsumption of carbohydrates, on which some stress has been placed in certain quarters. Goldberger, therefore, believes that meat and milk function advantageously by improving the quality of the protein in diets that have only a "narrow margin of safety." A deficiency of some essential amino-acid or acids is thereby prevented. This is in harmony with the recent report of a committee of inquiry regarding the prevalence of pellagra among Turkish prisoners of war in Egypt, which denies evidence of special infection in pellagra and ascribes it to a deficiency in protein, as gaged by its biologic value.

Goldberger's review admits, further, that the diets of the pellagrous households have a smaller average supply of the recognized vitamins than do those of the nonpellagrous, the disparity in supply being particularly marked with respect to the fat-soluble A factor. Furthermore, the mineral make-up of the diets of the nonpellagrous households will tend to be superior to that of the pellagrous households, or, at least, it is less likely to be deficient either as a whole or in any

1. Goldberger, Joseph: The Etiology of Pellagra, Pub. Health Rep. **29**: 1683, 1914.

of its elements. There is considerable evidence that a lack of the so-called water-soluble or antineuritic vitamin is not the foremost dietary defect in the genesis of pellagra, if, indeed, it is of any significance whatever. Milk, and to a lesser degree meat, may remedy the inorganic deficiency, if any exists. It is not irrational to suspect a possible concurrence of conditions facilitating dietary deficiencies of more than one sort. As stated in *Public Health Reports*, the somewhat lower plane of supply, both of potential energy and of protein, in the diets of the pellagrous households, though apparently not an essential factor, may, nevertheless, be contributory by favoring the occurrence of a deficiency in intake of some one or more of the essential dietary factors, particularly with diets having only a narrow margin of safety.

Further research is almost certain to discover more specifically the precise shortcomings in the food supply which are responsible for pellagrous symptoms. In the affected regions of the South, however, it seems clear that an increase in the availability of milk—perhaps by increasing cow ownership, as Goldberger and his colleagues propose—and of fresh meat by all-year-round meat markets at present represents the important practical measure to prevent and control pellagra.

THE FUMES OF IODIN

One of the important factors connected with therapeutics as a science is the method of administration of medicinal substances. Drugs may be given by mouth, by hypodermic or intravenous injection, by inhalation, by inunction or, less frequently, by the use of other entrances into the body. In choosing a method, the physical characters of the substance to be administered and the immediate effects of the substance on the body tissues with which it may come in contact must be especially taken into consideration.

These factors apply particularly in the case of substances like iodine, arsenic, mercury or the biologic products in which the mode of administration radically modifies the action. For some time manufacturers have urged substitutes for tincture of iodine, claiming that their substitutes were free from the undesirable properties of the tincture, and, at the same time, possessed special virtues which the tincture could not possess. More recently, attention has been directed to the administration of iodine in the form of vapor. The diffusing and penetrating powers of gases have particularly attracted the attention of therapists, since by this method drugs may be applied to rather inaccessible portions of the body, such as the lining of the lungs, the throat and the mucous membranes of the genito-urinary tract. Furthermore, it has been asserted that iodine in the form of fumes has increased combining powers, and is thus far more potent in effect than iodine administered by any other route. There do not seem to have been any adequate scientific investi-

gations of the subject, however, until the recently published results of Luckhardt and his collaborators¹ at the University of Chicago. In their experiments, both on man and on animals, accurately determined quantities of iodine were vaporized in a special device, and the fumes applied to the skin. At the same time, the tincture was applied to the skin of other persons as a control. Iodine was also applied to the skin of dogs with hyperplastic thyroid glands, and the effects on the gland, before and after administration, studied. Dogs were also used to determine whether iodine fumes were absorbed from the lungs. As a result of these investigations, which are reported in great detail, it was found that iodine, when deposited on the skin in the form of fumes, is absorbed. More iodine was recovered from the urine, following the application of the tincture, than was recovered following the use of the fumes. This result is explained by the authors on the ground that probably more iodine was actually applied, and that the iodine so deposited was held in combination with the protein during the process of coagulation of the latter by the alcohol of the tincture, leading to a state of continuous absorption. It is probable, furthermore, that the iodine deposited on the skin in the form of fumes is revaporized to some extent by the heat of the body.

Most important were the effects of iodine administered intratracheally in the form of fumes. Iodine given in this way seems to be rapidly and completely absorbed; but it was found that the administration of the fumes of iodine by inhalation through the respiratory passages, even in small quantities, is fraught with great danger. Such administration induces dyspnea; and when it is given in large quantities, acute and fatal pulmonary edema ensues within twenty-four hours. When respiratory disorders are present at the time of administration, the fatal edema supervenes very quickly. Thus far, no device designed to deliver fumes controls the dosage.

It is interesting to consider, as do the authors, the fact that the fumes of iodine have the same effect as those of two other halogens, bromine and chlorine. The results of these experiments with iodine fumes on the dog, as shown by necropsy findings, are practically identical with those reported by military surgeons as found in soldiers gassed with chlorine during the war.

The results of these researches are additional evidence as to how scientific research may confirm or deny conclusions based on empiric therapeutic observations. The work may well serve as a model for similar experiments, now being made, on the therapeutic use, intravenously, of such substances as nonspecific proteins or organic preparations of toxic drugs. The patient should at least have the chance that is afforded him by preliminary experiments, scientifically performed on animals in the research laboratory.

FACTORS IN AVERTING BACTERIAL INVASION THROUGH THE UPPER AIR PASSAGES

The upper air passages, including the mouth and nose, form an important portal of entry for micro-organisms into the body. The protection of the body against the dangerous invaders is varied in type. The blood may contain components which have a germicidal character or render innocuous the toxic products of bacterial growths. Long before the bacteria have an opportunity to reach the circulation, however, they may be inhibited in growth or destroyed. Thus, as we have pointed out,¹ the nasal mucosa may sometimes function to prevent infection from the virus of poliomyelitis. In the dissemination of the hemolytic streptococci which are so commonly present in the throat and tonsils, they may find their way into the alimentary canal; indeed, there is reason to suppose that they are constantly passing beyond the pharynx in large numbers. Yet so long as a potent gastric secretion is available, this type of micro-organism fails to pass beyond the stomach.²

As an illustration of the opposition offered by the mouth and its secretion to the free development of certain micro-organisms that have found entrance orally into the body, investigations by Bloomfield³ at the Johns Hopkins Hospital may be cited. He swabbed *Sarcina lutea*, a species nonparasitic and nonpathogenic for human beings, in large amounts on the tongue or nasal septum, or introduced it into the tonsillar crypts. Within a short time, usually from one to two hours, the micro-organisms could no longer be recovered there. Bloomfield introduced such large numbers of *Sarcina*, in proportions vastly greater than would be brought in by any natural mode of infection, that their rapid disappearance attests the remarkable efficiency of the mechanism present in the upper air passages for disposing of at least the particular organism mentioned. His analysis of the possible factors active in effecting this disposal indicated that the reaction of mouth secretions, mechanical action and other mouth bacteria play little if any part, but that the saliva and mouth secretions exert a prompt and marked bactericidal effect.

That different bacteria may be disposed of in quite unlike manner is further indicated by Bloomfield's latest studies of the fate of *B. coli* and *Staphylococcus albus*. In contrast with *Sarcina*, these are parasitic in human beings; and though usually nonpathogenic, they may at times produce disease. When they were swabbed on the tongue or nasal septum they usually disappeared within twenty-four hours; but when they were introduced into tonsillar crypts they could still

be recovered after somewhat longer intervals. In no case was a permanent carrier state set up. In explanation of the disappearance of *B. coli* and *Staphylococcus albus*, it seems unlikely that the mouth secretions play the part of the destructive or inhibitive agent. Since, however, inert particles placed in the upper air passages also disappeared at about the same speed as the bacteria, it is probable that mechanical influences are here involved; that is, "the organisms probably disappear because they are mechanically removed more rapidly than they multiply."

Evidently, then, protection must no longer be thought of as constant or uniform in character. Different species or types of micro-organisms may be disposed of in quite unlike ways in the upper air passages. The mouth secretions, the normal mechanical flushing processes in the mouth, nose and lacrimal passages, the unexplained potencies of the mucosa, the gastric juice, have all been demonstrated to take part in certain cases. What other mechanisms, if any, may aid in removing invading bacteria remains to be seen.

FACTS AND FICTIONS REGARDING TUBERCULOSIS

Now and then the public press stirs up the people to the possible menace to health which some of our habits may entail. If the warnings are justified on the basis of evidence, they must be welcomed. At the present time the public is particularly receptive to the lessons of science. The war demonstrated that science is a potent factor in life and in the world's work. The scientist must therefore be on his guard lest fiction creep in where facts are wanted; in other words, in order to retain a respectful hearing he must seek to prevent unfounded statements and half-baked theories from gaining recognition.

Recently the danger of kissing has been heralded anew in connection with tuberculosis. Although Richard Cabot¹ has warned the layman that osculation might well be dispensed with, the practice has not yet been abandoned. Hence it may be worth while to refer to the latest bacteriologic facts established by convincing methods.² Patients with tubercle bacilli in the sputum and saliva kissed sterile Petri dishes at different times in the day. Viable tubercle bacilli were demonstrated to be present at certain times in the day, though by no means always. Soon after coughing, the danger of transmission by kissing seems to be particularly marked. The possibility of transference of the micro-organism of tuberculosis to eating utensils, and thence if not cleansed to a second person, has likewise been borne out. On the other hand, the studies of the experts at the Trudeau Sanatorium² suggest

that the danger of the dust of rooms in a health resort has not yet been conclusively proved, and their experiments tend to belittle it. The same thing is true of the danger of eating utensils properly cleaned, of sanatorium telephone receivers, of door knobs handled by patients, and similar possibilities. Undue prejudice against the tuberculous would be a misfortune.

To the problem of laboratory diagnosis and prognosis of tuberculosis the Trudeau laboratories have also lately made contributions.³ It is pointed out that the number of tubercle bacilli present in a specimen as judged by the rough methods of examination usually employed does not give any definite information regarding pathologic activity that their mere presence does not afford. The same thing is true of such morphologic features as short bacilli, even in clumps. Much's granules and the presence of tubercle bacilli within certain cells in the sputum are likewise regarded as of no especial importance for the determination of pathologic activity, though elastic fibers in the sputum always are. Tubercle bacilli in the stools of adults have at least the same significance in respect to pathologic activity as when they occur in the urine. Of doubtful or negative value are various urine tests, namely, the diazo, urochromogen or methylene blue reactions. The mere figures of red and white blood cells are likewise without import.

Current Comment

THE MACROPHAGES IN BRAIN REPAIR

The rôle of the phagocytic cells that have of late been designated as macrophages, in some of the processes involving the repair and regeneration of injured bone, has recently been referred to in *THE JOURNAL*.⁴ By the preliminary use of so-called vital stains such as trypan blue and other azo dyes of the benzidin series—pigmentary substances which these phagocytic cells engulf and store with avidity—the location of the macrophages in various parts of the organism has become easier. Thus, Macklin⁵ found the dye-containing cells abundant in tissues immediately surrounding bone fractures. He concluded that "their mobilization in this region was for the purpose of assisting in the removal of the waste material, the result of the injury." This type of response in damaged and inflamed tissues is not dependent on the presence of bacteria. The attraction of cells with potent phagocytic power is not due to the chemotropism of microorganisms. It occurs in aseptic tissues and in widely different parts of the body. Thus, what is true in the case of bone repair has been duplicated in instances

of brain traumatism in recent researches of the Macklins.⁶ When lesions occur in the cerebral nervous substances the defunct tissue is rapidly absorbed, and this is accomplished by a temporary cellular mechanism, made up of young blood vessels, phagocytes and connective tissue—in fact, a granulation tissue. Fully developed macrophages soon begin their activity, and remain in such healing lesions for long periods. The dye-stained phagocytes may ingest considerable lipid material in the injured spots, and sometimes entire blood corpuscles are engulfed. According to Macklin, the macrophages seem to multiply by mitosis at the site of injury rather than to be transformed out of lymphocytes. They are apparently also recruited in part from the neuroglia, for hypertrophied neuroglia cells containing dye granules and other material may be found in the area of inflammation. Some also arise from the endothelium of the blood vessels; for endothelial cells in the injured region may become enlarged and filled with foreign material. They then behave like the other macrophages. Whether it is at the border of an infected abscess or in the midst of an aseptic area of defect, the function of the macrophages apparently is to ingest and transfer the products of tissue disintegration. Improved histologic technic has brought these beneficent scavengers into new and deserved prominence.

ORIGIN OF THE ACETONE SUBSTANCES IN THE BODY

The so-called acetone substances—acetone, acetoacetic acid and beta-oxybutyric acid—are excreted by the organism under conditions in which the metabolism, for some reason, is more or less deranged. That they are not derived in this way directly from sugar is made probable by the fact that the acetone substances are most likely to make their appearance when there is carbohydrate starvation; and the output may be checked in certain cases by carbohydrate administration. On the other hand, there is evidence for the belief that the acetone substances may be derived from both fats and proteins. In the case of the latter it is their amino-acid derivatives that are concerned in the ketogenesis. Not all of the amino-acids, however, are capable of contributing to an increased output of acetone substances under the determining conditions. Some of the amino-acids that are able to yield sugar in the organism doubtless may actually have an antiketogenic power. Current ideas as to the seat of formation of the acetone substances, which the clinician has come to look for so commonly in routine diagnostic procedures, have been derived from studies on surviving organs. Perfusion of these with blood containing various ketogenic substances in solution has shown that the liver may act as a place of formation.⁷ As experiments on the perfused muscles, kidneys and lungs, respectively, yielded negative results,

attention has become more directly focused on the liver as the chief organ involved in the perverted metabolism exhibiting ketogenesis. It has been known for some time, in corroboration of the presumable importance of the liver in this function, that the output of acetone substances is lower in dogs bearing an Eck fistula than in normal animals of the same species. This surgical device shunts the portal blood directly into the venous circulation without first passing through the liver, the blood supply of the latter being limited to that of the hepatic artery.* Kertess⁹ has verified this, particularly under conditions favorable to the exhibition of ketogenesis under the usual circumstances. When, however, a reversed Eck fistula operation was done whereby the blood supply of the vena cava was entirely sent through the liver before it returned to the heart for redistribution, acetonuria was greatly augmented. Hence, the dependence of the intensity of the output of acetone substances on the degree of participation of the liver in the circulation of acetone precursors—of the amino-acid leucin in the experiments of Kertess⁹—places this organ in the forefront of importance as the seat of ketogenesis more emphatically than ever.

THE SHORT AND CATCHY PROPRIETARY NAME

A laborer went to a Brooklyn physician for treatment and was given three prescriptions. One of the prescriptions, according to the *Food and Drug Bulletin* of the Department of Health, City of New York, called for "Laxol," the word being written on a piece of blank paper without directions. The drug clerk misread the prescription and dispensed an "original" bottle of "Lysol" which bore the usual poison label with skull and cross bones. The man drank the entire three ounces of Lysol and died half an hour later. The case is now in the hands of the District Attorney, the drug clerk being held under \$10,000 bail. "Laxol," as our readers know, is castor oil sweetened with saccharin and flavored with peppermint. There is no excuse for prescribing the product. The official Aromatic Castor Oil (Ol. Ricin. Arom.) of the National Formulary would answer every purpose served by the proprietary preparation.

A RECIPE FOR OLD AGE

In the memoirs of Baron de Grimm, written between the years 1753 and 1790, appears an account of the death of a member of the French Academy, a physician of eminence, one John J. de Mairan, at the age of 93. "He had arrived at this great age," say the memoirs, "without any infirmity, and preserved his good looks, his activity, as well as the entire use of his faculties to the last moment of his life." Until his last illness he scarcely missed going out a single day; he lived in the best society, dined out almost every

day, and passed the afternoon in making visits and the evening among his books. "He was exactly the kind of a person to live to a great age," says de Grimm; "his head was well formed, he had great equanimity of temper, great moderation in his passions, or rather he was destitute of passions; he had sensibility enough to engage the regard of those with whom he associated, and to contract those ties of intimacy which were sufficient for him, which have not indeed the charms of friendship, but which do not draw after them the same obligations. He had not warmth of heart enough to feel the necessity of an attachment which rules despotically; of a friend who disposes of us at pleasure, who forms the happiness or the misery of our lives: he had much prudence and foresight, paid great attention to himself, and was very methodical in whatever he did." Is this a text on geriatrics?

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Personal.—Dr. Arthur F. Stotts, Galesburg, who was shot, May 8, is reported to be improving slowly.—Dr. Elmer L. Crouch, Jacksonville, has become medical director of the Sanatorium for Nervous and Mental Diseases at Stamford, Conn.

Secretaries' Conference.—The annual meeting of the Secretaries' Conference was held in Rockford, May 18, and Dr. Henry A. Chapin, Jacksonville, was elected president; Dr. Lee O. Frech, White Hall, vice president, and Dr. Thomas D. Doan, Scottsville, secretary (reelected).

Hospital Notes.—The Moultrie County Red Cross and Tuberculosis Association have accepted the offer by W. A. Steele of a cottage in Sullivan to be used for a county hospital.—A site for the McDonough County Tuberculosis Sanitarium has been purchased at Bushnell, the consideration being \$2,000. Ground has been broken for a new nurses' home, which is being erected at a cost of \$125,000. The plan calls for a three-story brick building which is to be thoroughly modern.

Public Health Nursing Experiment.—The Illinois State Tuberculosis Association and Chicago School of Civics are cooperating in an interesting nursing experiment. Fourteen nurses from the class of public health nursing have been assigned for the month of May to make an extensive health and sickness survey in fourteen counties of the state. By this plan it is hoped to develop a knowledge of the tuberculosis situation and to induce the counties to support permanent public health nurses.

State Chapter of World War Medical Veterans Organized.—More than 100 medical officers who had served during the World War assembled in Rockford, May 19, at the call of Dr. John M. Dodson, Chicago, and organized the Illinois Chapter of the Medical Veterans of the World War, electing Dr. Joseph R. Hollowbush, Rock Island, as vice president for Illinois of the national organization and chairman of the state chapter; Dr. Wilbur H. Gilmore, Mount Vernon, secretary-treasurer, and Drs. Malcolm L. Harris, Chicago, and Samuel M. Wylie, Paxton, councilors.

State Medical Society Meeting.—The seventieth annual meeting of the Illinois State Medical Society was held in Rockford, May 18 to 20, under the presidency of Dr. James W. Van Derslice, Oak Park. On the second day, the president delivered his annual address; Dr. George W. Crile, Cleveland, the oration on surgery, entitled "Surgery of the Gallbladder and Ducts," and Dr. William Engelbach, St. Louis, the oration on medicine, entitled "Disease of the Pituitary Gland." Both of the orations were illustrated by stereopticon views. The following officers were elected: president, Dr. William F. Grinstead, Cairo; president-elect,

8. Fischler and Kossow: Vorläufige Mitteilung über den Ort der Acetonkörperbildung, *Deutsch. Arch. f. klin. Med.* **111**: 479, 1913. Kossow: Leber und Acetonkörperbildung, *ibid.* **112**: 539, 1913.

9. Kertess, E.: Zur Frage des Entstehungsortes und der Entstehungsart der Acetonkörper, *Ztschr. f. physiol. Chem.* **106**: 258 (July) 1919.

Dr. Charles E. Humiston, Chicago; secretary, Dr. Wilbur H. Gilmore, Mount Vernon (reelected); treasurer, Dr. Andrew J. Markley, Belvidere (reelected). Springfield was selected as the place for the next meeting.

CHICAGO

Joint Meeting.—May 26, the Chicago Medical Society and Chicago Ophthalmological Society held a joint meeting at which Dr. Dwight C. Orcutt read a paper on "The Importance of Early Treatment for Strabismus," and Dr. Richard J. Twinen, one on "Preventable Blindness," illustrated by lantern slides.

Personal.—Dr. Wesley Hamilton Peck, formerly president of the ophthalmologic section of the Illinois State Medical Society, was presented with a silver loving cup at the Rockford meeting, May 19, as an appreciation of his efforts in behalf of the section. Dr. Willis O. Nance made the presentation address.—William Gardner Cottrell, Ph.D., was awarded the tenth William Gibbs Medal at a dinner tendered by the Chicago Section of the American Chemical Society at the City Club, April 21.

INDIANA

New Hospital.—The Northwestern Indiana conference of the Christian church plans to build a hospital on the banks of the Tippecanoe River near Ora. The proposed institution will be maintained by the proceeds from a large endowment fund.

Fraudulent Eye Specialists.—The state board of health has received information from people living in Charlestown, that two men giving their names as Dr. Harper and Dr. Van Camp are touring the country representing themselves as agents of the state board of health, and as eye specialists and carry instruments for testing the eyes of patients, whom they secure in the name of the state board of health. It is said that their practice is for the most part on the eyes of children. According to Dr. John N. Hurty, secretary of the state board of health, neither of the men is a representative of the state board and a warning is issued against them.

IOWA

Personal.—Dr. Peter G. Grimm, Spirit Lake, has been appointed local surgeon of the Chicago, Milwaukee and St. Paul Railway.—Dr. Jeannette F. Throckmorton, Mason City, sailed for Europe, May 1.

Health Center Organized.—On May 12, Sioux City Health Center was formally organized and the building was open for inspection. The principal address was given by Dr. Herman M. Adler, Chicago, state criminologist of Illinois, and the opening day was known as Florence Nightingale Day.

Medical Women Elect Officers.—At the annual meeting of the State Society of Iowa Medical Women, held May 11, Dr. Lena A. Beach, Rockwell City, was elected president; Dr. Jennie M. Coleman, Des Moines, vice president; Dr. Mary K. Heard, Iowa City, secretary, and Dr. Eleanor M. Hutchinson, Des Moines, treasurer.

KANSAS

State Board Appointments.—Drs. William M. Earnest, Washington; Charles H. Ewing, Larned, and Clay E. Coburn, Kansas City, have been appointed to succeed themselves as members of the state board of health, for a period of three years.

State Medical Society Meeting.—The fifty-fourth annual meeting of the Kansas Medical Society was held in Hutchinson, under the presidency of Dr. Elmer E. Liggett, Oswego. Topeka was chosen as the place of next meeting and the following officers were elected: president, Dr. Clemens Klippel, Hutchinson; vice presidents, Drs. John R. Scott, Ottawa (reelected), Jacob L. Everhardy, Leavenworth, and Herbert Randles, White City; secretary, Dr. John F. Hassig, Kansas City (reelected); treasurer, Dr. Lewis H. Munn, Topeka (reelected).

MARYLAND

Gift to Johns Hopkins.—Instead of \$2,000,000, the Johns Hopkins University will receive \$5,541,401, under the terms of the will of the late Capt. Joseph Raphael de Lamar of New York. According to the terms of the will, the residuary estate is to be divided equally among the medical schools of Harvard, Columbia and Johns Hopkins universities, for the

advancement of preventive medicine and the study of dietetics.

State Medical Association's New Officers.—At the annual meeting of the Medical and Chirurgical Faculty of Maryland, held in Baltimore, May 11, 12 and 13, the following officers were elected: Dr. William S. Gardner, Baltimore, president; Drs. James H. Mason Knox, Jr., Baltimore, Arthur H. Hawkins, Cumberland, and Charles F. Davidson, Easton, vice presidents; Dr. Joseph Albert Chatard, Baltimore, secretary, and Dr. Charles E. Brack, Jr., Baltimore, treasurer.

Japanese Physicians Visit Baltimore.—The first of a large contingent of Japanese physicians, professors and students who are leaving shortly for Europe to begin their studies of European methods arrived in Baltimore recently. They are Dr. T. Hayao, assistant professor of medicine, Imperial University of Tokyo; Dr. B. Kure, a graduate of Columbia University, New York; Prof. B. Senju of Tokyo; Dr. C. Ookuni of Osaka, a graduate of Philadelphia and Boston dental colleges, and Dr. Shimade of Tokyo.

Praise for School for Blind.—The Red Cross Institute for the Blind at Evergreen, Baltimore, is the most advanced school for the war blind that has been established by any allied country, in the opinion of Capt. George Delvaux, head of Queen Elizabeth's Institute for the War Blind in Belgium. Captain Delvaux, who is studying methods at Evergreen, has visited schools for civilian and war blind in Italy, France and England. He came to Evergreen at the suggestion of Queen Elizabeth to whom he is directly responsible for the administration of the school for the blind established by her several months ago.

Final Transfer of Soldiers at Fort McHenry Hospital.—The transfer of 219 patients from U. S. Army General Hospital No. 2, Fort McHenry, to the Walter Reed General Hospital at Washington, May 18, marked the closing days of the fort as a United States Army hospital. The detachment, consisting of thirty-one "litter patients" and 188 "sitting patients," were taken to Washington, D. C., on a special hospital train. The patients transferred included twenty-six officers, 191 enlisted men and two civilians, and represented 177 surgical and forty-two medical cases. The U. S. Public Health Service will take over the fort, May 31.

Personal.—Dr. Henry R. Carter, assistant surgeon-general, U. S. P. H. S., has returned to Baltimore after spending two and one-half months with the Rockefeller Foundation party fighting yellow fever in the Piura district of northern Peru. He hopes to return to Peru within a month, if his health permit, to take charge of the work, succeeding Gen. William C. Gorgas, adviser in sanitation for Peru, who has been called to South Africa.—Dr. Robert M. Lewis recently flew from Baltimore to Cambridge, Md., in a hydroplane in response to a request to hurry to the Cambridge Hospital where many surgical cases had accumulated. The trip consumed fifty-five minutes, while by boat it would have taken four hours.—Surg. James A. Nydegger, U. S. P. H. S., on duty at Baltimore has been transferred to Quebec for duty, and after a thirty-day leave of absence, will assume his new duties. Senior Surg. Thomas R. Payne will come to Baltimore to take charge of the hospital and other public health matters in this city.

MASSACHUSETTS

Healer Sentenced to Imprisonment.—"Prof." Fred Laplante, Worcester, on May 3, is said to have been sentenced to the house of correction for a term of six months on three charges of larceny, all three sentences to run concurrently. Three other charges alleging practice of medicine without a certificate or registration were placed on file.

Qualification Vaccination of All Schoolchildren.—The Somerville Medical Society has placed itself on record as advocating without qualification vaccination of all schoolchildren as a protection to the community against the ravages of smallpox, and as expressing its condemnation of Senator Joseph O. Knox, Somerville, who allowed his personal feelings to influence him on public measures, as a betrayer of public trust. The bill extending the law regarding the vaccination of children of public schools to children who attend private schools was defeated. Senator Knox is said to have been active in the defeat of this bill and also in the support of a bill to repeal the existing laws regarding vaccination.

Personal.—Dr. Robert B. Greenough, Boston, has accepted the chairmanship of the New England Committee on the Control of Cancer, and has already taken steps to effect a district organization.—William J. Brickley, Boston, has

been appointed medical examiner (coroner) for Sussex County succeeding Dr. Oscar Richardson, Boston, resigned. —Dr. Theobald Smith has been given the M. Douglas Flattery medal and \$500 in gold by the Harvard corporation. The reason of the award is given as follows: "Theobald Smith, working on Texas fever in cattle, demonstrated for the first time that the micro-organism of an infectious disease could be transmitted through the agency of an invertebrate host." —Dr. Milton J. Rosenau has been elected to the Charles Wilder professorship in preventive medicine and hygiene, founded by Charles Wilder and Miss T. E. Wilder, Cambridge.

Report of Communicable Diseases.—The department of public health has sent an appeal to the physicians of the state calling attention to the fact that a few physicians have failed conspicuously to fulfil their obligations regarding the reporting of communicable disease. For this reason the division of registration in medicine of the department of civil service and registration and the department of public health are cooperating in the following manner: Names of physicians who do not report cases of diseases dangerous to the public health to their local boards of health shall be furnished to the department of public health. The department of public health will present to the division of registration in medicine of the department of civil service and registration these names with the proper evidence of neglect to report such diseases. Where it is positively known that the physicians persistently neglect and refuse to report such diseases, a hearing will be granted by the division of registration in medicine of the department of civil service and registration to the offending physician, giving him the opportunity to show why his license to practice medicine should not be suspended.

MICHIGAN

Society Organized.—At the meeting of the physicians of the medical societies of Antrim, Charlevoix, Emmet, Grand Traverse, Leelanau and Wexford counties held in Charlevoix, the Northwestern Michigan Medical Society was organized with the following officers: president, Dr. Robert B. Armstrong, Charlevoix; vice president, Dr. George W. Fralick, Maple City, and secretary-treasurer, Dr. Buell H. Van Leuven, Petoskey. Arrangements were made to hold a clinic in Petoskey in September and another at Cadillac later in the year.

MISSISSIPPI

Personal.—Dr. Theodore P. Barnes has been elected superintendent of the state colony for feeble-minded. —Dr. Hiram Byrd, director of the department of hygiene of the University of Mississippi, has resigned to accept the position of director of the department of hygiene of the University of Alabama. —Dr. Francis M. Sheppard, Richton, has been appointed assistant superintendent of the Mississippi State Charity Hospital, Jackson.

New State Officers.—At the thirty-third annual meeting of the Mississippi State Medical Association held in Jackson, May 11 and 12, under the presidency of Dr. Felix J. Underwood, Aberdeen, Laurel was chosen as the next place of meeting, and the following officers were elected: president, Dr. John W. Barksdale, Winona; vice presidents, Drs. Horace H. Kinney, Okolona, William A. Johns, Corinth, and Lawrence B. Hudson, Hattiesburg; Dr. Thomas M. Dye, Clarksdale, secretary (reelected), and Dr. James M. Buchanan, Meridian, treasurer (reelected). The annual address was delivered by Dr. Seale Harris, Birmingham, Ala., on "Food Poisoning."

MISSOURI

Health Officers to Meet.—The week from June 14 to 19, inclusive, has been designated as public health week, and at this time the first formal conference of health officers ever held in the state will convene under the auspices of the University of Missouri School of Medicine and the state board of health.

New Officers.—At the annual meeting of the Southeastern Missouri Medical Association held in Farmington, Dr. Warren C. Patton, Cape Girardeau, was elected president; Dr. John A. Van Amburgh, Burfordville, vice president; Dr. Elam J. Nienstedt, Blodgett, recording secretary; Dr. William S. Hutton, Fornfelt, corresponding secretary, and Dr. William R. Goodykoontz, Caledonia, treasurer.

Occupational Therapy School.—A school for occupational therapy has been opened in the City Hospital at St. Louis under the direction of the Missouri Association for Occupa-

tional Therapy. A large room has been assigned for the workshop, fitted up with work benches and work tables some of which are specially designed for patients in wheel chairs. Miss Cora Ault is superintendent of occupational therapy for the hospital, and with two assistants teaches handicrafts to the patients. Similar schools have been in operation for some time in the City Sanatorium and the Barnes Hospital.

NEW JERSEY

"Christian Scientist" Fined.—Andrew Walker, a "Christian scientist" of Bloomfield, is said to have been convicted of manslaughter in connection with the death from diphtheria of his 9 year old daughter and sentenced, on May 10, to pay a fine of \$1,000. Walker failed to summon a physician and had the child treated by three Christian science practitioners.

Progressive Legislation.—During the present session of the New Jersey legislature, four bills of interest to physicians have been considered. Two of these providing for delaying the issuance of marriage licenses to sufferers from venereal disease have already been passed unanimously by both houses. The other two deal with the reporting by physicians of syphilis and gonorrhea and are drawn to provide state laws conforming to federal recommendations on the subject.

NEW YORK

New Public Health Centers.—Public health centers, including tuberculosis, venereal disease and dental clinics, and a child welfare station have been established at Olean, Geneva and Fredonia.

Bill for Purchase of Radium.—There is at present before the New York State Legislature a bill known as "a bill appropriating \$250,000 for the state institute for the study of malignant disease, for the purchase and use of radium," introduced by Senator Gibbs and Assemblyman Seelbach on behalf of Dr. Harvey R. Gaylord, director of the state institute, Buffalo.

Amendment of Law Governing Employment of Town Physicians.—The law relating to the employment of town physicians has been amended by an act of legislature so that a town may now combine with an adjoining town in the employment of a town physician who may reside in either of the two places. The amended law strikes out the clause limiting residence within a radius of 8 miles of the town boundary, and also the one limiting the salary to \$1,000 per annum.

Governor Urged to Veto Chiropractic Bill.—The board of managers of the state charities aid association has passed resolutions urging the governor to withhold his approval of the bill recently passed by the legislature to "define and regulate the practice of chiropractic" on the ground that approval of the bill would constitute a real and serious danger to the health of the people of the state by giving public recognition and official license to persons claiming to be able "to locate and adjust by hands misplaced or displaced vertebrae of the human spine for the purpose of relieving the nerve pressure caused thereby." This recognition and license, it is held, would be interpreted by large numbers of people as being equivalent to the giving of authority to practice medicine.

Endorsement of Health Center Plan by Dental Society.—The New York State Dental Society, at its recent meeting in Albany, unanimously adopted a resolution approving the provisions of the health center bill which was introduced into the last legislature by Senator Sage and Assemblyman Machold. The resolutions lay particular stress on the great need for provision for proper care of the mouth and teeth of the rural population, and for instruction in the disastrous physical results of neglect to provide such measures. These resolutions provide for the appointment of a committee from the State Dental Association for the purpose of cooperating with other organizations concerned with or interested in the public health of the state, with a view of securing favorable action on the health center bill at the next session of the legislature.

Typhoid Death Rate Decreases.—During 1919, the typhoid fever death rate in this state decreased to the lowest figure yet recorded, namely, 3.3 per hundred thousand. In 1906, the rate was 19 per hundred thousand. In commenting on these figures, a recent bulletin of the New York State Department of Health compares the condition of the water supplies of the state in 1906 with that of the present time. In 1906, there were about 400 public water supplies which served a population of about 6,100,000. Nearly fifty of these sup-

plies received some purification and served a population of about 700,000. In 1919, there were 510 public water supplies serving a total population of about 8,700,000. Of these water supplies 125 were purified either by filtration, chlorination or both, and served a population of approximately 7,000,000. In other words, the number of people receiving pure water increased 1,000 per cent. during this period.

Intensive Course in Syphilis.—Two intensive courses in syphilis under the auspices of the Rochester Health Bureau will be held in the state hospital and the general hospitals and dispensaries, June 14 to 19 and June 21 to 26, inclusive. They will be in charge of Dr. George W. Goler, health officer, of Rochester. The courses include: first, the history and municipal control of syphilis, and second, clinical lectures and demonstrations of, and participation in darkfield work with the living treponema; the technic of Wassermann tests and reactions; the preparation of arsphenamin, technic of its administration in the arm, femoral, jugular and scalp veins, and the superior longitudinal sinus; methods of giving mercury; spinal punctures, and cytology and chemistry of spinal fluid. The course will be free. Each course is limited to fifteen students, and applications must be sent in to the Health Bureau, Chestnut and James Streets, Rochester, for the first course before June 12, and for the second course, before June 19.

New York City

Endowment Fund Increased.—The president of the New York Post-Graduate Medical School and Hospital announces that up to May 20, \$1,264,801.57 had been subscribed toward the \$2,000,000 endowment fund of the institution.

Flatbush Society Election.—At the annual meeting of the Flatbush Medical Society held in Brooklyn, May 12, Dr. Harold A. Morris was elected president; Dr. Richard M. Mills, vice president; Dr. William F. C. Steinbugler, secretary, and Dr. George A. Merrill, treasurer.

Fund in Memory of Dr. Cragin.—The trustees of Columbia University announce that former patients of the late Dr. Edwin B. Cragin have raised a fund of \$3,500 in his memory to be used in social service work at the Sloane Hospital for Women. They also announce a scholarship in the College of Physicians and Surgeons through a gift of \$6,000, by Wallis S. Turner in memory of his father, Charles W. Turner.

New Officers.—At the annual meeting of the Women's Medical Association of New York City, held May 19, under the presidency of Dr. Emily Dunning Barringer, the following officers were elected: president, Dr. Ethel D. Brown; vice presidents, Drs. Eleanor Parry and Mary Alice Asserson; corresponding secretary, Dr. Isabel Taylor MacMillan (reelected); recording secretary, Dr. Frances Cohen, and treasurer, Dr. Allis E. Hascall (reelected).

Reeducation of Hospital Patients.—An effort to reeducate a group of women who remain for a considerable time in hospital wards because of venereal disease is being carried on at the Kingston Avenue Hospital, Brooklyn. The New York City Visiting Committee in cooperation with Mrs. Wilcox of the board of education and Miss Marshall of the Manhattan School Board has sent a well-trained teacher to these women. A similar class has been carried on at the city hospital with excellent results.

Personal.—Dr. William T. Doran has received \$15,000 in settlement of a bequest of \$25,000 under the will of Margaret A. Howard, which was contested by other heirs.—Dr. Adolphus Monae-Lesser has received a bequest of \$80,000 under the will of Joseph Auditore. It is reported that the will will be contested.—Dr. John M. Wheeler was elected secretary of the board of surgeons of the New York Eye and Ear Infirmary, May 18.—Dr. Harry Feldman, Brooklyn, has been appointed assistant to the chief surgeon of the Greenpoint Hospital.—Dr. Israel S. Wechsler has been appointed adjunct in neurology in Mount Sinai Hospital, New York City.—Dr. John A. Ferguson, Brooklyn, has been appointed a member of the board of education of New York City.

First Aid to the Industrial Worker.—The Bureau of Public Health Education of the Department of Health in the City of New York has issued Keep Well Leaflet No. 19, entitled "First Aid to the Industrial Worker," prepared by Dr. Samuel Dana Hubbard, superintendent of the division of industrial hygiene. About 350,000 industrial injuries are reported each year in New York state, the majority of which are in New York City, and in about 15 per cent. of these, infections have increased the serious nature of the injury.

This percentage would have been reduced materially by proper application of first aid. The leaflet first considers why overhauling the human machine is necessary, gives rules for the avoidance of accidents, suggestions for first aid, information for the employer, and then devotes sixteen pages to concise and well-considered instructions to laymen for first-aid treatment of common injuries and disorders, advising the laymen what to do and what not to do.

OKLAHOMA

New Hospital.—The Southern Baptist Convention has under construction a new fifty-bed hospital at Cushing. This hospital will care for a large district in the oil field section of the state.

Personal.—Dr. Finis W. Ewing, Muskogee, has been appointed superintendent of health for Muskogee and Muskogee County.—Dr. Virgil Berry, Okmulgee, announces his retirement after more than thirty years of practice.

Medical Society Notes.—An organization known as the Oil Field Medical Association has recently been organized in Oklahoma, its membership includes all the active medical men of Cushing, Yale, Oilton, Quay, Shamrock and Drumright. Dr. William J. Neal, Drumright, is president, and Dr. J. Walter Hough, Jr., Cushing, secretary-treasurer.—At the meeting of the Logan County Medical Society held in Guthrie, April 22, Dr. Pauline Q. Barker was elected president.—At the annual meeting of the Quay County Medical Association held in Parker City, Dr. James C. Hawkins, Blackwell, was elected president, and Dr. William A. T. Robertson, Ponca City, vice president.

PENNSYLVANIA

Commission to Revise State Laws Named.—On the commission to revise and codify the laws relative to the insane and the feeble-minded were named Judge Isaac Johnson, Media, chairman of the state board of public charities; Dr. Theodore Diller, Pittsburgh, Drs. Owen Copp and Charles H. Frazier, Philadelphia, and C. Herr, Harrisburg.

Barber Shop Inspection.—Medical inspection of barber shops in the central part of the city was started, May 19, under the direction of the health department and the survey is to extend to barber shops all over the city. After inspections are completed, Dr. Furbush, director of public health and charities, will issue certificates to each barber shop found in a sanitary condition. A centralized medical clinic where all barber journeymen will be examined is one of the chief things for the future, according to Dr. Furbush. While there is no ordinance to supervise the work there are enough health laws to compel barber shops to clean up. The inspection was started through the request of proprietors of large barber shops who desired a certificate for their places.

Personal.—Dr. Iden M. Porster, Greensburg, has resigned as a member of the state board of health.—Dr. Joseph J. Meyer, Johnstown, has been appointed chief of the genito-urinary dispensary at Johnstown.—Dr. Patrick H. Weeks, Warren, has been appointed physician to the Northern Indiana Penitentiary, Michigan City.—Dr. Hugh J. Coll, Connellsville, has been elected local surgeon of the Baltimore and Ohio Railway, succeeding Dr. Elliott B. Edie, resigned.—Dr. Frank D. Glenn, Erie, who was a member of the Montour County Medical Society in 1912, has returned to the State Hospital for the Insane at Danville, as a member of the staff.—Dr. G. Roberta Fleagle, Hanover, will soon leave for Colgan, China, as a medical missionary under the Methodist board. She will have charge of hospital work, paying particular attention to diseases of women and children, and will be the only woman physician among 125,000 Chinese people.—Dr. Roland Jessop, York, assistant county medical director of York County, has resigned.

WEST VIRGINIA

Personal.—Dr. Frank Lemoyne Hupp, Wheeling, has accepted the chairmanship of the West Virginia Cancer Committee and has appointed the following division chairmen: Drs. John E. Cannady, Charleston division; Wade H. St. Clair, Bluefield division; Chester R. Ogden, Clarksburg division; William W. Golden, Elkins division; Carter S. Fleming, Fairmount division; J. Ross Hunter, Huntington division; Charles S. Hoffman, Keyser division; John N. Simpson, Morgantown division; J. Howard Anderson, Marytown division, and Mary V. McCune Rossa, Martinsburg division.

WISCONSIN

Hospital Enlarged.—Plans are completed which will double the size of the Deaconess Hospital, Green Bay. A new unit is to be built which will give the hospital a capacity of 120 beds.—Dr. Daniel W. Lynch has reopened his hospital at West Bend which he closed when he went into military service.

Resign from Medical Faculty.—Ten members are reported to have resigned from the faculty of the Marquette University School of Medicine on account of a disagreement between them and the president of Marquette University over several ethical questions, one of which is that of sacrificing an unborn infant when necessary to save the life of the mother. Those who have resigned are:

Drs. Louis M. Warfield, Professor of Clinical Medicine; John L. Yates, Professor of Clinical Surgery; Emerson A. Fletcher, Director and Professor of Genito-Urinary Surgery; Carl Henry Davis, Associate Professor of Obstetrics and Gynecology; Chester M. Echols, Associate Professor of Obstetrics and Gynecology; Frederick J. Gaenslen, Director and Associate Professor of Orthopedic Surgery; James D. Madison, Associate Professor of Medicine; Arthur J. Patck, Associate Professor of Medicine; Arthur W. Rogers, Associate Professor of Neurology; Charles H. Stoddard, Associate Professor of Medicine.

CANADA

Personal.—Sir Adam Beck was elected president of the London Health Association, April 10, after a ninth term.—Dr. Ira De La Matter, Mono Road Station, Ont., was presented with the Royal Humane Society Medal at the reception of the returned soldiers of the County of Hastings. Dr. De La Matter saved two persons from drowning in the Trent Canal.—Dr. Edgar C. Barnes, assistant superintendent of the Homewood Sanitarium, Guelph, has been appointed medical superintendent of the Hospital for Mental Diseases, Selkirk, Manitoba.

GENERAL

Thoracic Surgeons Hold Meeting.—At the third annual meeting of the American Association of Thoracic Surgeons held in New Orleans, May 1, Dr. Rudolph Matas, New Orleans, was elected president; Dr. Walton Martin, New York City, vice president, and Dr. Nathan W. Green, New York City, secretary-treasurer.

American Physicians' Association Election.—At the annual meeting of the Association of American Physicians held in Atlantic City, N. J., May 4 and 5, Dr. William S. Thayer, Baltimore, was elected president; Dr. Herbert C. Moffitt, San Francisco, vice president; Dr. Thomas McCrae, Philadelphia, secretary; Dr. Thomas R. Boggs, Baltimore, recorder, and Dr. Joseph A. Capps, Chicago, treasurer.

Coming Meetings.—The thirty-seventh annual meeting of the American Climatological and Clinical Association will be held in Philadelphia, June 17 to 19, under the presidency of Dr. Lawrason Brown, Saranac Lake, N. Y., with headquarters at the Bellevue-Stratford Hotel.—The thirty-second annual meeting of the American Pediatric Society will be held at the Moraine Hotel, Highland Park, Ill., May 31 to June 2, under the presidency of Dr. Thomas S. Southworth, New York City.

Conference of Health Authorities.—The eighteenth annual conference of state and territorial health authorities was held in Washington, D. C., on May 26 and 27. This conference was called at the instance of Dr. Hugh Cumming, Surgeon-General of the Public Health Service. A program for the two days' conference included discussions on "Rural Sanitation," "Public Health Administration," "Endemic Index and Communicable Disease Control," "Better Morbidity Reports," "Initiation of a Nation-Wide Health Campaign," "Coordination of Effort and Promotion of Efficiency in Field of Sanitary Engineering," "Framing of a National and State Policy for the Production of Clean Milk in Adequate Quantities," "Migration of Tuberculous Persons," "Provisions for Lepers," "Child Hygiene," and "Malaria."

Home Economics Association.—The thirteenth annual meeting of the American Home Economics Association will be held at Colorado Springs, Colo., June 24 to 29, inclusive, with headquarters at the Antlers Hotel, under the presidency of Edna N. White of Detroit. The science section, which is naturally of most interest to physicians, holds its sessions on June 28, when papers will be presented by Mrs. Agnes Fay Morgan of the University of California, on "The Contribution of European Experience on Low Diets to Our Teaching of Dietetics," and by Helen R. Thompson of the Kansas Agricultural College, on "Effect on Young of Alternate Periods of Suppression of Growth and Refeeding: Experi-

mental Data on Albino Mouse," and by Major David Klein, Chicago, on "Scientific Preparation of Gland Extracts and Their Use in Feeding in Cases of Malnutrition."

Senate Committee Restore Appropriation to Combat Venereal Diseases.—Fears entertained by physicians and social workers that the national government's campaign against venereal diseases would be stopped because of lack of funds will be allayed by the action of the Senate Committee on Appropriations. This committee has restored to the Sundry Civil Bill appropriations amounting to \$785,000 which were heretofore stricken out of that bill on the floor of the House of Representatives. Within the past week Senators have received hundreds of telegrams and letters from mayors of cities, church federations, officials of the Y. M. C. A. and city health authorities approving of the splendid work accomplished by the Bureau of Venereal Diseases of the national government and asserting that it would be a national calamity if this salutary work were not continued.

Anesthetists Meet.—At the annual meeting of the American Association of Anesthetists held in New Orleans, last month, resolutions were adopted that the association place itself on record as unalterably opposed to the employment of lay anesthetists, nurse anesthetists, who have not been graduated from recognized medical and dental colleges and have not been licensed to practice medicine or dentistry; and agree to inaugurate and prosecute legislation to protect the medical and dental professions and the public from such inadequately educated and trained anesthetists whenever such action is necessary and pledged its cooperation with the government in securing specialists in several branches of medicine in the medical department of the Navy and the medical department of the Army. The following officers were elected: president, Dr. Joseph E. Lumbard, New York City; vice presidents, Drs. Frank L. Richardson, Boston, and Eleanor C. Seymour, Los Angeles, and secretary-treasurer, Dr. F. Hoeffler McMechan, Avon Lake, Ohio.

Bequests and Donations.—The following bequests and donations have recently been announced:

Cambridge, Mass., Hospital, a bequest of \$70,000 by the will of Mrs. James A. Wollson.

Children's Home Society, Jackson, Miss., for the erection of an annex for housing children having contagious or communicable diseases, a donation of \$10,000, by Mrs. S. W. Johnson.

Home for Incubables, Philadelphia, \$10,000, Methodist Hospital, \$5,000 and Frankfort Hospital, \$500, by the will of Mary Anne Elliott. Episcopal Hospital, Philadelphia, \$500, by the will of Florence W. Holbrook.

Lankenau Hospital, Philadelphia, \$5,000, by the will of Gustav A. Schwartz.

St. Vincent's Home, Maternity Hospital, Philadelphia, and one other institution, \$4,000, by the will of Michael Corrigan.

Children's Home, York, Pa., York Hospital and Tressler's Home, York, each \$1,000, and Society to Protect Children and Aged Persons, \$500, by the will of Miss Amanda Smyser, York, Pa.

Servants' Relief and Incurable Cancer, New York City, \$1,000, by the will of Ann Hogan.

For a new hospital at Denison University, Newark, Ohio, a donation of \$25,000, by Mrs. F. C. Whistler, Hillsboro.

Association for Research in Nervous and Mental Diseases.—On the initiative of the New York Neurological Society, an association has been organized to foster research in neuropsychiatric diseases. Meetings are to be held yearly. At each meeting only one subject will be discussed. The meetings will be conducted by a commission whose members will act as an investigating body on the presentations and theses submitted at each annual meeting; and at the conclusion of the meeting the commission will prepare and publish such material as it deems fit. Subjects will be given out from one to three years in advance of the meeting. The commission has decided on New York for the first meeting late in December, 1920. The subject for discussion is "The Acute Nonsuppurative Infections of the Nervous System." Each member is to pay a fee of \$5 yearly to the secretary-treasurer of his local neurologic society, who will transmit all funds to the secretary-treasurer of the research association, Dr. Foster Kennedy. The neurologic societies of Baltimore, Boston, Brooklyn, Chicago, New York City, Philadelphia, Pittsburgh, San Francisco and Washington, D. C., have thus far been extended invitations to membership. The chairman of the organization committee is Dr. Walter Timme, New York City; Dr. Frederick Tilney, New York City, is chairman of the committee on arrangements for the first annual meeting.

FOREIGN

Physicians Wanted for the Dutch Colonies.—A German exchange quotes the *Nederlandsch Staatscourant* of Jan. 1, 1920, to the effect that positions are open to fifteen foreign

physicians in the Netherlands colonial medical service and fifteen more are to be open later. The contract calls for three or five years' service, with salary of 3,000 and 5,000 gulden and free transportation to and from the Dutch East Indies. Applicants must state whether they wish the shorter or longer contract or will serve in combating the plague, and enclose credentials. Address Departement van Kolonien.

British Medical Association Meeting.—The eighty-eighth meeting of the British Medical Association will be held at Cambridge, from June 29 to July 2, under the presidency of Sir Clifford Allbutt, who will deliver the president's address, Tuesday evening, June 29. The scientific and clinical work will be divided into twelve sections, and sessions will be held Wednesday, Thursday and Friday. The scientific discussions are scheduled for the morning sessions, while the afternoons will be taken up by clinical and laboratory demonstrations. A popular lecture by Dr. G. S. Graham-Smith on the evening of July 2 will mark the close of the meeting.

Professor Pawlow.—Part of a letter from the Russian physiologist, Prof. J. P. Pawlow, of Petrograd, dated August, 1919, was republished in *Science* March 5, 1920. The letter was alleged to be an appeal to his friends in Kieff to send him some provisions as he was starving. The quoted sentence was: "Instead of science, I am busy peeling potatoes." This appeal has been copied the world around, but protests have also been published, expressing doubts as to its authenticity, as the two statements conflict. If he has potatoes to pare, he cannot be starving. It is also pointed that owing to the scarcity of servants, many professors now are engaged at times in peeling potatoes. No further news has been received direct from Petrograd regarding the matter.

Congress of Physiology.—A Congress of Physiology will be held at Paris, July 16-20, under the presidency of Prof. Charles Richet, and physiologists of allied and neutral countries are invited to attend. Titles and abstracts of papers to be read before the congress should be in the hands of the secretary not later than June 1. The abstracts should not exceed twenty-five lines. Information is also requested whether animal demonstrations or lantern slides will be used to illustrate the papers, and what animals and apparatus will be required. In connection with the congress, there will be an exhibition of laboratory apparatus and instruments. The fees for affiliation (35 francs) should be sent to M. Lucien Bull, at the office of the congress, Sorbonne, 1 rue Victor Cousin, Paris V.

Repeal of Extension of Health Insurance in Germany.—THE JOURNAL mentioned recently, page 1411, the new law whereby benefits of state health insurance were extended to all persons with incomes up to 20,000 marks. The *Deutsche medizinische Wochenschrift* now brings word that the National Assembly has yielded to the influence brought to bear by the profession, and has repealed this law, reducing the income limit to the old figure 12,000 marks. "By the vigorous and concerted action of the medical men of the country," the editorial states, "the profession has won an extraordinary victory. With amazing promptness the government submitted a new bill to the assembly; it was adopted and goes into effect May 3. The profession can see from this what can be accomplished by purposeful action, and that it is impossible for physicians' just demands to be ignored. It is to be hoped that they will proceed henceforth in this same united manner when it is a question of their vital interests."

Victory for the United Profession in Spain.—The health officers in Spain, the *médicos titulares*, have always been in the pay of the local municipal authorities, and this has led to numerous abuses. In many towns the local authorities have put off paying the *titulares* until they are years in arrears, and the health officials have suffered from actual want. A concerted movement has been on foot for some months to have the officially appointed health officers, prison physicians and veterinarians paid by the state, like the post-office employees. This has finally been secured, both houses having voted favorably on it after two all-night sessions of discussion. The victory was won at last by a single vote, the *Siglo Médico* relates. Cortezo, director of the *Siglo Médico*, was the leader of the forces in the senate. In an editorial commenting on the victory the appeal is made anew for "all physicians, health officers and others, high and low, to make their influence felt in the elections, refusing their support to every candidate, whatever his politics, who will not promise to aid and promote the wishes of the medical profession and sanitary reforms. Legislators who will work for the betterment of the race are good, whatever their

political beliefs. . . . Health is the first thing; living comes before theorizing."

Deaths in the Profession in Other Countries

Dr. C. Esmein of Paris, on the editorial staff of the *Archives des maladies du cœur*, aged 38.—Dr. A. Lapuente of Buenos Aires.—Dr. J. Veranes of Madrid.—Dr. Herculano Penna Jr. of Floriano, Dr. B. dos Anjos of Bahia, and Dr. Climerio de Oliveira, professor of gynecology in the medical school at Bahia, all of Brazil.—Dr. Alejandro García Aragón of Turrialba, Costa Rica, a graduate of Yale, aged 48.—Dr. G. T. Chalybaeus of Dresden, aged 82.—Dr. J. H. Spiegelberg of the Ebenhausen Sanatorium for children, near Munich.—Dr. W. Merkel, Hofrat, of Nuremberg, aged 87.—Dr. Rauzier, professor of clinical medicine at the University of Montpellier, one of the founders of the Société neurologique and author of numerous works, including a treatise on the pathology of the elderly, aged 58.

LATIN AMERICA

New Home of the S. Paulo Medical Society.—The Sociedade de Medicina e Cirurgia of S. Paulo, Brazil, recently celebrated its twenty-fifth anniversary and at the same time took possession of its new home, rua do Carmo, 6.

Antirabies Institute in Nicaragua.—The *Brazil Medico* states that an antirabies institute was recently organized at Managua in Nicaragua. It is said to have been made possible by the generosity of the late president of Mexico, and is to be called by his name, Carranza Institute.

Chair of Physiology in Paraguay.—The medical faculty of the University of Paraguay at Asunción asked the minister of foreign affairs of Brazil to select an incumbent for the chair of physiology for a term of three years. He referred the matter to the Rio de Janeiro medical faculty, and they submitted the names of four candidates. The one selected, Dr. Roquette Pinto, has been livre docente of physiology at Rio for some time.

CORRECTION

Section on Laryngology.—In the minutes of the Section of Laryngology, Otology and Rhinology of April 30, which appeared in THE JOURNAL of May 15, page 1393, it is said, "Dr. Joseph L. Goodwin, Tazewell, Tenn., presented combined forceps and bronchoscope." This is an error, as this instrument was presented by Dr. A. Ellis Goodloe of Chattanooga, Tenn.

Government Services

Appropriation for History of War Approved in Senate

The efforts in behalf of a medical and surgical history of the World War now promise to be successful. The Senate Committee on Appropriations has made provision for the publication of such history by the insertion of an amendment in the Sundry Civil Bill that \$75,000 be expended for this purpose. It is generally understood that the Senate will adopt this amendment which was approved by formal resolutions of the American Medical Association at its annual session in New Orleans this year. Surg.-Gen. M. W. Ireland made a special appeal to the Senate Committee in behalf of this appropriation.

Health Conditions of the Army

Health conditions among the troops in the United States continue excellent. The admission and noneffective rates, while showing a slight increase over last week, are still unusually low; and only a few cases of communicable diseases are reported from the various camps and stations, but nowhere have they assumed epidemic proportions. There were thirty-eight cases of measles reported against fifty-one the preceding week. The Western Department reports six admissions for diphtheria and Brooks Field, Texas, reports eight diphtheria carriers. Camp Taylor and the Western Department each report two new cases of pneumonia, and Camps Dix, Grant, Sherman and Fort Logan each report one. The death rate for disease, 1.5, is the lowest since September, 1917. There were only four deaths from disease, one each from pneumonia, empyema, cardiac dilatation, and surgical shock. Excellent health conditions prevail among the American Forces in Germany. There was but one death among these forces, the cause of which is not given.

Criticisms of American Universities

At a meeting of the Royal Colonial Institute, Sir A. E. Shipley read a paper on "Universities in Canada and the United States." He pointed out that Canada was better provided in proportion to population with universities and seats of education than these islands. London, with its population of 8,000,000, was content with one university, while Canada, with not much more than half that number of persons, had a larger number of universities than the United Kingdom. The cost of university training in Canada was considerably less than in the United Kingdom. Unlike the American universities, the Canadian had retained the British system of honors. In Toronto and McGill, the training in medicine was abreast of the best on the European continent. In the universities of the United States, the number of students was amazing. In the discussion that followed, Sir George Parkin said that in the American universities education was given on a democratic scale to great crowds, while Cambridge tried to educate men individually. One of the greatest results of the Rhodes scholarship would be that American students would be taught to realize that no teaching could be more efficient and inspiring than the individual system. Sir Gilbert Parker said that the mass method of teaching was wrong, and that the individual system of the English universities was by far the best.

The Place of Public Opinion in Preventive Medicine

Lecturing on this subject, Sir George Newman, chief medical officer of the ministry of health, said that we now knew that the causes of disease were not something arbitrary, capricious, occult or accidental, but an effect of causes in large and increasing measure controllable. For the first time public and personal health were purchasable. The problem could be stated in a word. The English people were suffering from impaired physique. Ten years of medical inspection in elementary schools had shown that no fewer than 1,000,000 children were so defective that they could not derive reasonable benefit from their schooling. The returns for 1914-1916 disclosed that more than half the insured persons in England and Wales received medical treatment every year and that there were upward of 14,000,000 weeks of sickness a year, most of which was due to preventable disease. In the year following Nov. 1, 1917, there were 2,425,184 examinations of recruits. Of this number only 36 per cent. were found to be of full normal health and strength, and 40 per cent. presented marked physical disabilities. The coming of the ministry of health meant a new sort of attack on the strongholds of disease. It meant increased intervention by the state, improved organization, central and local, and a bolder policy. But a factor in reform in some ways more important than all these was an educated community. We should never win through to a high physical standard until the great mass of the people were educated sufficiently to be able to choose the way of health. The dietary of the great mass of workers consisted of bread, beer, tea, pickles, canned meat, a bit of bacon and a piece of cheese. Appetizing cookery, freshly prepared food, healthy conditions and sound digestion were often absent. The reason was not poverty, but lack of knowledge. Sir George Newman emphasized the value of games and recreation. The nation ought to have available a complete scheme of educational and recreative gymnastics to train body and brain, combined with games,

swimming, field sports and tennis. Invalidism, diseases and premature death were due to a relatively small number of morbid conditions, of which a large proportion were preventable. Thus, four principal diseases—pulmonary tuberculosis, influenza, poliomyelitis and cerebrospinal fever—were now known to be conveyed from person to person by inhalation of the causal microbe. Protection could be secured only by safeguarding one person from another on the individual scale. A clean mouth, clear breathing passages, abstinence from spitting, sneezing, coughing or shouting or breathing at other people would go a long way toward prevention. Other groups of maladies, such as dyspepsia, septic wounds and disease contracted by infection, could be considerably lessened by dissemination of simple knowledge as to their causation. The prevalence of venereal disease was a stain on our civilization. A further purpose of enlightened public opinion in regard to preventive medicine was that the assent of the community might be won for sanitary reform and its consent secured for sanitary government, imperial and local. Mere legislation would prove abortive if not supported by intelligent public opinion. The admirable work of the voluntary health societies could hardly be overestimated, and such a campaign as the national health week was particularly valuable.

The Medical Examination of Aeronauts

The air ministry has issued a schedule for the medical examination of civilian pilots, navigators and engineers. The candidate must be at least 19 years of age, of good heredity in respect to nervous stability, and free from any disease, injury or abnormality likely to interfere with efficiency. In addition to the general medical examination there are special flying tests. Among these is one for "expiratory force," as shown by readings on a U tube manometer. When the expiratory force is under 80 mm. of mercury, the subject will probably be incapable of sustained effort in routine aerial work. The special mental tests, such as the reaction time tests, to which the Italians and others have paid special attention, have not been adopted to any large extent, because we feel that a history of aptitude for various sports requiring eye is of equal value, as compared with a somewhat elaborate experiment on a special occasion under circumstances frequently trying to the applicant.

The Leper Problem

An important congress, summoned by the mission to lepers, of missionaries and physicians has been held at Calcutta under government auspices. The conference recognized that leprosy is a slowly contagious disease, in which the nasal discharge is frequently infectious before the stage of ulceration is reached; that, though the disease is not hereditary, children are peculiarly susceptible to infection, and that segregation is the most effective measure for reducing the prevalence of the disease. It was recommended that voluntary segregation should be encouraged except in the case of pauper lepers, in respect to whom compulsory powers should be obtained and settlements established. In view of the considerable fecundity of lepers, especially of females, separation of the sexes was advised. When this was not practicable, married lepers should be allowed to live together only on the understanding that any children born to them should be taken away at the earliest possible age. A bill has been introduced into the imperial legislative council following closely these recommendations.

Class Fertility

The declining birth rate seems to be an inexhaustible topic, always presenting new phases for discussion. At the Statistical Society, Dr. T. H. C. Stevenson, superintendent of statistics in the general register office, read a paper on the

fertility of the various social classes from the middle of the nineteenth century to 1911, based on information obtained in the last census as to the duration of marriages and the number of children born and surviving. He pointed out that in considering the differences in fertility between the various sections of the population it was necessary to bear in mind the differences in their child mortality. Taking the population as a whole, large families implied high, and small families low child mortality. It was possible, therefore, that the small families of the middle classes were in part due to the low mortality of their children, as well as the latter to the smallness of their families. In a typical case—wives married at 20 to 25 whose marriages had lasted from fifteen to twenty years—child mortality rose from 102 per thousand born in one-child families to 339 in twelve-child families and 407 in those of more than twelve children. This was due to the rapidity of births implied as well as to their number. At the same time, high fertility did not necessarily involve high mortality. Agricultural laborers were 37 per cent. more fertile than textile workers, but the mortality of their children was 35 per cent. less. The census figures not only showed that fertility increases downward in the social scale, but also suggested that this difference is of comparatively recent origin—in other words, that the defective fertility of the classes which are presumably the most successful and efficient is a new fact, the consequences of which are not yet apparent and will have to be faced. Comparatively little class variation in fertility is observed in marriages contracted before 1861. More recent marriages have been subject to the influences, whatever they may be, that have led to the fall in the birth rate from 1877 onward. Their fertility has rapidly declined, and at the same time the class variation has greatly increased, which suggests that artificial restraint is the main cause of the decline. This is confirmed by several other facts. The decline began in higher social strata and spread gradually downward; occupied mothers show a very low fertility, and infertility increases in the higher classes with increase of marriage duration up to twenty-five years. The comparatively low infant mortality in the less fertile classes goes very little way toward compensating for their low fertility. The least fertile classes are those that marry late in life. The fertility of occupied wives was found to be considerably lower than that of wives whose husbands had the same occupation. Thus, the fertility of male teachers was 70 per cent. of the average of all classes, but that of female teachers was only 52 per cent.

Osler's Will

Sir William Osler left an estate of the gross value of \$80,000 with a net personalty of \$58,000. He left his medical and scientific library (as cataloged) to the McGill University, Montreal, and all other property to his wife. At her death or earlier, if she should wish it, his residence, 13 Norham Gardens, Oxford, is to be given to the dean, canons and governing body of Christ Church as the residence of the regius professor of medicine.

The American Hospital in London

The plans for the American Hospital in London, already described in *THE JOURNAL*, are considerably advanced. Mr. Taft has accepted the office of president in America. Lord Reading is president in England, with Lord Bryce as vice president. American residents in London have formed themselves into a committee, which includes many prominent names, and steps are being taken to incorporate the institution according to the laws of the state of New York. It is hoped to open a temporary building this autumn. The hospital is intended to become the principal research center in Europe for American graduates. British physicians are in

sympathy with the work, the committee including several eminent names, such as Sir Arbuthnot Lane, Sir Humphry Rolleston and Sir Bland-Sutton. There is also a committee in the United States which includes Drs. W. J. and C. H. Mayo, George W. Crile, A. J. Ochsner and Franklin Martin. The two medical committees will work together. In July the authorities of the hospital will entertain Dr. C. H. Mayo at dinner.

A Substitute for Bismuth Subnitrate

Since the war it has become difficult to procure a suitable quality of bismuth subnitrate. Moreover, all of the salts of bismuth have increased in price to such an extent that their use has become prohibitive to a large class of patients. This state of affairs has led to a search for an efficient substitute. Some years ago, after several regrettable cases of poisoning from bismuth subnitrate, it was proposed to substitute the subcarbonate. This suggestion had no regard for the question of economy, for bismuth subcarbonate is as costly as the subnitrate. It is therefore interesting to call attention to a recent communication before the Academy of Medicine, by Doctor Georges Hayem, formerly professor of clinical medicine at the Faculté de Médecine de Paris. He suggests that in place of bismuth subnitrate, there be employed kaolin, a white clay used in the manufacture of crockery and porcelain. Kaolin, an amorphous powder composed of silica and oxids of aluminum, iron and magnesium is almost insoluble in water and organic fluids. Hayem first employed it in 1915 as a substitute for bismuth subnitrate in a case of gastric ulcer. Favorable results were obtained and he extended its use to all conditions for which he had usually prescribed bismuth subnitrate, especially for the relief of gastralgia. If thoroughly cleansed, kaolin has no pronounced taste, and it can be employed mixed with water without a corrective. Still, to avoid loathing or a disagreeable sensation of taste, the kaolin may be made aromatic by adding to each 40 gm. one drop of essence of anise or six drops of essence of mint. It should be noted that Prof. J. Stumpf of Würzburg once recommended finely powdered kaolin for the treatment of acute and chronic intestinal infections, especially cholera. According to him, the remedy acts in a purely mechanical fashion by encompassing the micro-organisms in some way and preventing their further multiplication.

Mouth Washes and the Tax on Pharmaceutic Specialties

By an act of Dec. 30, 1916, a tax was imposed on pharmaceutic specialties for which curative and prophylactic properties are claimed. This means that the tax in question does not apply to toilet preparations, such as mouth washes. But this is, however, not true if the manufacturer or merchant attributes therapeutic or prophylactic virtues to the mouth wash. Thus a perfumer was prosecuted in the court at Riom for selling a bottle of proprietary mouth wash without the tax stamp. The court had acquitted the merchant on the basis that as the product was a mouth wash, it came under the class of toilet specialties and not of pharmaceutic specialties. The representative of the bureau of indirect taxes carried the case to the court of appeals on the ground that the bottle was wrapped in a circular which announced that the mouth wash was a remedy for caries and toothache, whereupon the court ruled that the merchant had violated the law of 1916 by advertising the product as a therapeutic substance.

Honorable Distinction to the Faculty of Medicine of Nancy

The French government has recently directed public attention to the noble conduct of the personnel of the faculty of

medicine of Nancy (the teaching personnel, nurses and employees) who, for the entire duration of hostilities, at a short distance from the front, successfully continued its work with the limited resources left after military mobilization, united by a common spirit of solidarity for teaching as well as for the care of military and civil victims in the hospitals under its charge. Despite the repeated dangers to which Nancy was exposed, especially in 1918, at a time when by order of the government all universities should have been closed, the medical school remained open because of its obligations to the hospitals, thereby setting an example of constant energy, of cool courage and of the modest performance of daily duty.

The Evolution of Pathology and Medicine

In a series of books, "Les sciences d'aujourd'hui," under publication by Masson et Cie, there is a very interesting work on medicine by Prof. H. Roger, dean of the Paris medical faculty. The introductory paragraph contains a very accurate definition of medicine: "a science in its methods of study, an art in its applications." Both phases are the subjects of instructive discussion, touching on all that which might be called the philosophy of medicine and which may well merit the attention of all physicians.

Because of their originality, several chapters are worthy of special mention: those dealing with the evolution of pathology and with the evolution of medical science.

In his study of the evolution of pathology, Roger shows that certain diseases tend to decrease in frequency and to become confined to certain regions; it may be hoped that they will disappear entirely before long. Leprosy furnishes the most striking example: in the thirteenth century, there were 19,000 leprosariums in Europe, 2,000 in France alone. Today, leprosy is localized to a few countries, while in France only sporadic cases are found near Marseilles and Nice. On the other hand, there are diseases which appeared at a certain epoch and which do not seem destined to disappear so soon. The eruptive fevers, for instance, originated in the sixth century, and cerebrospinal meningitis was unknown until the nineteenth century. Devastating epidemics were preceded by cosmic disturbances, by great variations in temperature and pressure or by earthquakes. Virchow once hoped that a thorough study of these various causes would lead to reliable prediction of the imminence of epidemics, analogous to meteorologic forecasts. But what is even more interesting is the influence of social conditions on the change in pathology. Thus, industrial progress has greatly increased poisonings from adulteration; by extending its fields of activity, industry has also increased the varieties of occupational poisoning; although various prophylactic measures have succeeded in reestablishing the equilibrium by reducing the frequency of these accidents.

Proceeding from the point that the social condition of a country influences the morbid reactions and has a special effect on psychopathic manifestations, Roger wonders what influence the war will exercise on the insanities. It is probable, he says, that a profound change will be effected: the war has wiped out our old utopias and has developed the sense of realities. Men will no longer be solicitous for position and honor but they will pursue pleasure and riches with much greater brutality. The present agitations and the new difficulties of existence will certainly have their effect on us and they will lead to another evolution of the psychopathies.

On the other hand, after tracing the historic evolution of science, Roger arrives at the conclusion that this has profoundly modified the traditional methods of medicine. In times past, diagnosis was based on very simple methods of examination, and therapeutics consisted of pharmaceutical pre-

scriptions; today certain delicate diagnoses require complex procedures and explorations which demand special installations. Roger forecasts, therefore, that sooner or later diagnostic establishments will be organized where persons with chronic diseases, overworked and even well subjects will stay for several days, and on a case history card will be recorded the functional condition of each organ. It will also be easy to give such advice on diet and hygiene as is advisable and to point out prophylactic measures necessary to avoid menacing danger.

Exchange of Professors

Exchange of professors with foreign universities, for a long time practiced by the Faculté des lettres de Paris is gradually extending to the other faculties. Thus the council of the University of Paris has recently approved a course in the law school by M. André Mercier, dean of the faculty of Geneva. On this point the *Gazette des hôpitaux* says that there is every reason to hope that the medical faculty, under the active impulsion of the dean, Professor Roger, will soon enter into exchange relations with English and American universities.

Faculty Appointments

Doctor André Broca, agrégé, has been appointed professor of medical physics of the Paris medical faculty, succeeding Professor Weiss, recently appointed dean of the medical faculty of Strasbourg.

Student Welfare

The University Society for Student Welfare recently held a meeting at the Sorbonne under the presidency of M. Appel, rector of the University of Paris. The society is designed to give material and moral support to all students who may feel in need thereof. Various lines of activity have been proposed: the establishment of numerous student centers (foyers); the organization of a service of information, intelligence and medical assistance; the consolidation of extant associations and houses for students, and similar measures.

Consulting Medical Commission of the Aviation Service

There has recently been appointed by the undersecretary of the state for aviation a consulting medical commission, with instructions to publish a scientific program of research for the medical section of the technical service of aviation, to assure the necessary scientific authority to medical measures submitted for the approval of the undersecretary of state, and in a general way to decide all related questions such as the testing of physical fitness or the treatment of aviators. The commission under the presidency of Dr. Georges Guillaumin, includes Drs. Pierre Duval, André Broca, Camus, Crouzon and others.

Marriages

JOHN IGNATIUS WISEMAN, Baltimore, to Dr. Katherine Isabel Tate Slattery Fricka of Boston, April 24.

GUY MANNERING OWSLEY, Thorntown, Ind., to Miss Charlotte M. Smith of Columbus, Ind., April 6.

HILMAR GEORGE MARTIN, Milwaukee, to Miss Grace A. Waring of Washington, D. C., April 27.

THOMAS DUGAN BAXTER, Chilton, Texas, to Miss Eunice Lotridge of Nashville, Tenn., April 14.

HARRY JAY PITTOCK to Miss Maude Mae Burgoon, both of Hastings, Neb., May 12.

WALTER L. DREWRY to Miss Esse C. Morris, both of El Paso, Texas, April 18.

CHARLES KLAUS STULIK to Miss Zdenka Spatney, both of Chicago, May 10.

DANIEL LEONARD GOLANN to Miss Ethel Block, both of Brooklyn, May 8.

Deaths

Lindon Bulkley Cady, New York City; Columbia University, College of Physicians and Surgeons, New York City, 1914; aged 31; a member of the Medical Society of the State of New York; assistant surgeon, U. S. N. R. F., and relieved from active duty April 10, 1919; clinical assistant in the New York Skin and Cancer Hospital; died in St. Luke's Hospital, New York City, May 13, two days after a surgical operation.

Edward Sealy, Newark, N. J.; Bellevue Hospital College, 1884; aged 71; a member of the Medical Society of New Jersey; attending physician to the Home for the Friendless, Newark; attending surgeon, throat department, New York Eye and Ear Infirmary, and senior surgeon to the Hospital for Women and Children, Newark; died in that institution, May 11, from cerebral hemorrhage.

Charles Lee King ☉ Pasadena, Calif.; Chicago Medical College, 1880; aged 66; once secretary of the Los Angeles County Medical Society, and president of the Pasadena Branch of the Los Angeles County Medical Society; for three years medical superintendent of the Alma (Mich.) Sanitarium; president of the Pasadena Y. M. C. A. from 1915 to 1918; died, May 5.

Arthur Ellison Midgley ☉ Whitewater, Wis.; University of Illinois, Chicago, 1904; aged 41; lieutenant-colonel, M. C., U. S. Army, and discharged Sept. 23, 1919; cited for bravery by his divisional commander and General Pershing, April 19, 1918; died, May 20, from the effects of a gunshot wound of the heart, self-inflicted, it is believed, with suicidal intent.

James Lindsey Porteous ☉ Yonkers, N. Y.; L.R.C.P. and S. (Edin.), 1867; M.R.C.P. (Edin.) 1878; F.R.C.S. (Edin.), 1879; consulting surgeon to St. Joseph's Hospital; a fellow of the New York Academy of Medicine, and formerly vice president of the Westchester County Medical Society; aged 78; died, May 13.

Rudolph R. Seidel, Bedford, Ohio; Western Reserve University, Cleveland, Ohio, 1893; aged 52; a member of the Ohio State Medical Association; who was struck by an interurban car in Bedford, April 21, suffering a fracture of the skull; died in St. Alexis Hospital, Cleveland, May 5.

William Joseph Dismuke ☉ Ocilla, Ga.; University of Georgia, Augusta, 1901; aged 48; a member of the Georgia Surgeons Club; local surgeon for the Seaboard Air Line, and general surgeon for the Ocilla Southern Railroad; died, May 13, following an operation for appendiceal abscess.

Archibald Haas, Chicago; Bennett Medical College, Chicago, 1882; College of Physicians and Surgeons, Chicago, 1886; aged 70; died, May 22, from the effects of a gunshot wound, self-inflicted, it is believed, with suicidal intent, while despondent on account of ill health.

Charles Edwin Boddiger ☉ Chicago; College of Physicians and Surgeons, Chicago, 1893; aged 52; captain, M. R. C., U. S. Army, and discharged Dec. 14, 1918; who was operated on for glioma of the brain, March 10, died in Wesley Memorial Hospital, Chicago, May 22.

Thomas Henry Landor ☉ Canton, Ohio; McGill University, Montreal, 1884; aged 57; contract surgeon, and captain and assistant surgeon, U. S. V., from 1898 to 1908, with service in the Philippine Islands; died, May 6, from hypertrophy of the liver, and gastric ulcer.

Waldemar F. Lungerhausen, Mount Clemens, Mich.; University of Pennsylvania, Philadelphia, 1897; aged 42; a member of the Michigan State Medical Society and president of the Macomb County Medical Society; died, May 1, from cerebral hemorrhage.

William Addison Elrod, Albertville, Ala.; University of the South, Sewanee, Tenn., 1900; aged 50; a member of the Medical Association of the State of Alabama; died in Gadsden (Ala.) General Hospital, May 7, a week after a surgical operation.

Francis C. Maloney, Avilla, Ind.; Charity Hospital Medical College, Cleveland, 1866; aged 75; a member of the Indiana State Medical Association; died in Sacred Heart Hospital, Garrett, Ind., May 4, a few days after a surgical operation.

Jacob Prinzing ☉ Nampa, Idaho; University of Minnesota College of Medicine, Minneapolis, 1901; aged 44; lieutenant, M. R. C., U. S. Army, with service at Camp Lewis, Wash.,

and discharged Jan. 23, 1919; died, May 7, from acute peritonitis following an operation for gastric ulcer.

Persis White, Winnetka, Ill.; Northwestern University Woman's Medical School, Chicago, 1894; for eight years resident physician at the North Shore Health Resort, Winnetka; died, May 20, in St. Mary's Hospital, Rochester, Minn.

Dewitt C. Joyner, Memphis, Tenn. (license, Arkansas); aged 71; a practitioner since 1861, and for more than half a century a practitioner of Mississippi County, Ark.; surgeon in the Confederate service during the Civil War; died, May 5.

Charles Milo Holcomb, Seattle; Jefferson Medical College, 1887; aged 60; a member of the Washington State Medical Association; died in the Seattle General Hospital, May 3, two days after a surgical operation.

Harvey Gilbert, Bay City, Mich.; New York Homeopathic Medical College, New York City, 1874; aged 73; at one time coroner of Bay County and health officer of Bay City; died, May 2, from cerebral hemorrhage.

Alzine M. Castlebury, Williamsport, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; a member of the Medical Society of the State of Pennsylvania, aged 61; died, April 24, from rheumatism.

Warren Randall Gilman ☉ Worcester, Mass.; Harvard University Medical School, 1888; aged 58; for many years a member of the staff of the Worcester City and Worcester Memorial hospitals; died, May 2.

Alwin Hugo Schwab ☉ Brooklyn; College of Physicians and Surgeons in the City of New York, 1890; aged 52; while making a professional call, May 15; died from heart disease in the home of the patient.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE FRAUD ON THE PUBLIC AND ON THE PROFESSION

HOSTETTER'S BITTERS

"Hostetter's Celebrated Stomach Bitters" contains 25 per cent. alcohol. So far as is shown by a careful investigation made by the A. M. A. Chemical Laboratory, the amount of this nostrum that can be taken is limited only by the individual's capacity for alcohol! The label, as the law requires, declares the presence of 25 per cent. alcohol; that is, "Hostetter's Bitters" is one half the strength of "straight" whisky. The recommended daily dose is six tablespoonfuls (3 ounces). This means that a person taking Hostetter's Bitters—strictly according to directions—gets as much alcohol daily as would be obtained from nearly two bottles of beer (alcohol strength $3\frac{1}{2}$ per cent. by volume) or from $1\frac{1}{2}$ ounces of "straight" whisky.

The alcohol content of Hostetter's Bitters seems to have been a variable quantity. As long ago as 1878 the question of the beverage use of this nostrum in Alaska was under consideration by the Internal Revenue Department. A letter from the Commissioner of Internal Revenue at that time stated that Hostetter's Bitters was sometimes sold by the glass by retail liquor dealers and also sold "by the drink" in saloons in Sitka. In January, 1883, the Treasury Department notified the Collector of Customs at Sitka that, in its opinion, Hostetter's Bitters "should be excluded from Alaska under the executive order of Feb. 4, 1870, forbidding the importation of distilled spirits into that territory."

In THE JOURNAL of Sept. 8, 1883, there was published in full a long communication from the Office of Internal Revenue addressed to the manufacturers of Hostetter's Bitters, in a reply to their question as to whether or not it was necessary for the retailers of the "Bitters" to take out a special license for its sale. The Internal Revenue officials declared that a chemist in the Department of Agriculture had analyzed Hostetter's Bitters and had reported finding 32 per cent. alcohol—whether by weight or volume was not stated—64 per cent. water and 4 per cent. of extracts. The chemist reported further that the stuff was "flavored with various essential oils, as oil of anise, coriander, etc., and contains some vegetable bitters, such as gentian, cinchona, etc." The chemist very naturally declared that Hostetter's Bitters contained much more alcohol than was necessary to hold the other ingredients in solution. Commenting on this analysis, the Commissioner of Internal Revenue said:

"Containing, as it does, no deleterious drugs and only 4 per cent. of anything like a drug, I should probably be entirely justified in deciding outright that one who sells it for any purpose is a retail liquor dealer. . . ."

The Commissioner admitted, however, that the case was complicated by the fact that for many years the government

had "classified the preparation as a proprietary medicine and collected stamp tax upon it." As a result, the Commissioner said that he would not decide at that time whether in the abstract Hostetter's Bitters was a medicine or not. For, said he:

"Should I hold it to be a medicine, I should probably do violence to an almost irresistible tendency of the mind to conclude that no genuine medicine needs so much whisky and so few drugs in it, unless under very unusual circumstances. On the other hand, should I decide that it is no medicine at all, I would be confronted by a ten-years' quasi recognition by this office to the contrary, as well as by the practice of many people who use it as such."

The upshot of this case was that the Commissioner decided to "let the use give character to it"; when the stuff was, apparently, sold as a *bona fide* medicine no action would be taken; when it was sold to be drunk as an intoxicating beverage the seller would be taxed accordingly. The Commissioner's letter closed with the statement:

"This seems to me to be the true rule, and an article containing so little that is even nominally medicinal as yours does ought and will be subject to very close scrutiny as to its use."

In 1906, the state chemists of North Dakota reported that their analysis showed Hostetter's Bitters to contain 43 per cent. of alcohol by volume, with only $4\frac{1}{2}$ per cent. of total

solids, and the chemists reported that the principal portion of the total solids was sugar.

In 1907, after the Food and Drugs Act went into force, and the amount of alcohol had to be declared on the label, Hostetter's Bitters for a time contained 39 per cent. alcohol, the label reading in part:

"Averaging thirty-nine per cent. of alcohol by volume in finished product, being only sufficient to hold in solution the extracted medicinal properties of barks, roots, herbs and seeds contained therein."

Later, the amount of alcohol was reduced to 25 per cent. and the labels were changed to read, as they read today:

"Averaging twenty-five per cent. of alcohol by volume in finished product, being only sufficient to hold in solution the extracted medicinal properties of barks, roots, herbs and seeds contained therein."

In 1914, the state chemists of Connecticut analyzed the nostrum and reported finding nearly 25 per cent. of alcohol, a small amount of quinin and about $4\frac{1}{2}$ per cent. of solids "all but 0.8 per cent. of which is sugar."

The kind and quantities of drugs (other than alcohol) in Hostetter's Bitters have, so far as we know, never been divulged, to the consumers at least, by the manufacturers. Formulas purporting to represent the composition of this nostrum had variously given, as some of the ingredients, gentian root, blessed thistle, cinchona bark, calamus root, Colombo root, orange peel, rhubarb, cinnamon and cloves.

In April, 1920, the A. M. A. Chemical Laboratory completed an analysis of Hostetter's Bitters. The complete details of analysis will, as usual, be published in the Annual Reports of the Laboratory. The essential part of the report follows:

LABORATORY REPORT

"The specimen of Hostetter's Stomach Bitters examined was a pale amber-colored liquid having a bitter taste, a neutral reaction and an odor resembling a mixture of anise and orange flavors. The label declared the presence of 25 per cent. of alcohol but gave no further information concerning the composition of the preparation. The preparation

SOME ALCOHOL EQUIVALENTS

HOSTETTER'S BITTERS CONTAINS 25% ALCOHOL,
THE DAILY DOSE RECOMMENDED IS SIX
TABLESPOONFULS OR THREE OUNCES!

The Daily Dose of Hostetter's Bitters
contains as much Alcohol as does
the Beer in
these bottles
or the "Straight"
Whiskey in
this glass.

(ALCOHOL, 25%) (CONTENTS, 18 OZ.)
(SIX TABLESPOONFULS) (CONTENTS, 3 OZ.)
(ALCOHOL, 50%) (CONTENTS, 11 OZ.)
(ALCOHOL, 50%) (CONTENTS, 21 OZ.)

Miniature reproduction of one of the educational posters prepared by the Propaganda Department of THE JOURNAL. In the originals, which measure 22 by 28 inches, the bottles and glass are reproduced natural size.

is described, among other things, as 'a corrective and mild cathartic.' Alcohol was determined and 24.72 per cent. by volume was found. On evaporation the preparation gave 4.8 gm. of residue per 100 c.c. of which about 80 per cent. was cane sugar. The ash amounted to about 0.045 gm. per 100 c.c. The small percentage of ash excluded the presence in medicinal quantities of such purgative salts as magnesium citrate, magnesium sulphate and potassium sodium tartrate. Extraction of the faintly acidified solution with ether gave 0.023 gm. of ether extract per 100 c.c. This residue was of a pale greenish color and had a bitter taste suggestive of gentian. No active medicinal substances could be identified in this residue.

"The ether extract from 100 c.c. of the preparation was mixed with milk sugar and swallowed by a healthy man without producing any symptoms. This demonstrated the absence of appreciable amounts of podophyllum, scammony and jalap.

"Iodids, bromids, heavy metals, emodin-bearing (laxative) drugs, and phenolphthalein were absent. Traces of tannin were found. A mixture of alkaloids was present in which quinin and cinchonidin were identified. This, together with the occurrence of tannin, suggested the probable presence in Hostetter's Stomach Bitters of extractives from cinchona. The total alkaloids amounted to 0.167 gm. per 100 c.c. or about $\frac{3}{4}$ grain per fluid ounce. With the exceptions of the alcohol and the cinchona alkaloids no other physiologically active ingredient was found.

"Six fluid ounces of the preparation (6 doses) were dealcoholized, the solution evaporated, the residue mixed with milk sugar, the mixture placed in capsules and the capsules swallowed at one dose by a healthy man. No effects were noted.

"From the results of the examination it is evident that alcohol is by far the most active ingredient in Hostetter's Stomach Bitters. The preparation is probably a hydro-alcoholic extract of small quantities of cinchona and possibly small amounts of other relatively inactive drugs. The analysis failed to reveal the presence of any drugs in quantities which would prevent the preparation being used as a beverage."

It is obvious from the analysis just given that, as stated at the outset of this article, the use of Hostetter's Bitters as a beverage is, apparently, limited only by the individual's tolerance for alcohol. One point is worth attention: Hostetter's Stomach Bitters has for a good many years been recommended for malaria among numerous other conditions. The A. M. A. chemists found small quantities of quinin and cinchonidin present. In order to get a daily dose of quinin equal to 15 grains, the minimum amount the Pharmacopeia recommends as an antimalarial, it would be necessary to take nearly twenty ounces of Hostetter's Bitters daily. This would necessitate swallowing an amount of alcohol equivalent to about 10 ounces daily of "straight" whisky.

Many of our readers will remember THE JOURNAL's reference to an episode that occurred three years ago. The Baltimore Sun of Feb. 24, 1917, carried a news item from Danville, Va., to the effect that the police in that town had had to deal with a large number of "drunks" each of whom admitted that he became intoxicated on "a certain proprietary medicine which contains 25 per cent. alcohol." A telegram from THE JOURNAL to the Chief of Police of Danville asking for the name of the proprietary medicine in question, brought the laconic reply "Hostetter's Bitters."

During the recent past several nostrums of the alcohol type have markedly modified their formulas. "Vinol," which used to contain 18 per cent. alcohol, now contains 10 per cent. "Manola," which used to contain 18 per cent., now contains 15 per cent.; "Peruna," which long contained 20 per cent. alcohol, now contains 12. "Wine of Cardui," which also for years contained what the manufacturers declared was the irreducible minimum of 20 per cent., now contains 10. "Warner's Safe Cure," put out by a concern that used to be what was practically a subsidiary company to a distilling concern, for years had 15.5 per cent. alcohol; it is now nonalcoholic. The motives that brought about these changes are unimportant; the facts are the vital elements. Whether some of these manufacturers have received hints from the Internal Revenue Department, whether the increased cost of alcohol or whether both have been responsible for the modifications, we do not know.

Whatever may have been the cause, or causes, of the changes in the case of the products just mentioned, they do not seem to have operated in the case of Hostetter's Bitters. To this fact we respectfully direct the attention of the Internal Revenue Department.

Correspondence

INDICATIONS FOR OPENING THE DRUM IN ACUTE MIDDLE EAR INFECTIONS

To the Editor:—In the main, I am in agreement with the views set forth by Dr. L. E. La Fétra in his article on "Acute Middle Ear Infection in Children" (THE JOURNAL, May 1, 1920, p. 1222). But I must question his judgment regarding the indications for incision of the membrana tympani. Dr. La Fétra states that when the temperature is high, pain acute and the bulging marked, he deems it best to incise the drum. Further, he says that the infrequency of mastoid involvement and other complications, and the very satisfactory results of conservative treatment are his justification for awaiting further indications than those of the day of onset. Again, he states that if tenderness elicited by pressure on the tragus increases, if there is tenderness of the tip of the mastoid and the temperature remains high after twenty-four hours and the bulging persists, incision is necessary.

The incision of the drum—especially in a young child—is indicated, according to my experience, which is not a small one both in public and in private practice, if there is bulging, notwithstanding the absence of pain or abnormal temperature. There is another indication besides the danger of the involvement of the mastoid, etc., for freeing the exudate from the drum cavity when the drum is bulging, namely, the preservation of the hearing function. I have seen rosy-cheeked children who were cheerful, took their food, were playful and slept well, with the drum cavity full of pus. In some cases the disease was discovered in the routine of a general examination, because the child did not thrive.

To leave ears alone because of the absence of pain and abnormal temperature is to invite disaster, especially in measles and scarlet fever. The hearing function has been destroyed without the presence of pain or abnormal temperature; chronic suppuration of the middle ear has followed without pain or fever, or both. The tympanic structures in a child are soon destroyed. Owing to the exceedingly thin covering of the inner wall of the tympanum with periosteum, the lower portion of the promontory especially is very poorly protected. I have frequently heard the statement from intelligent general practitioners that as there was no pain or high temperature there was no occasion for examining the ears. I have seen mastoids destroyed without pain in the adult. In tuberculous subjects, young or old, there is little or no pain. In infection with *Streptococcus mucosus*, pain may be absent, with little or no rise of temperature.

In some cases the process is fulminating, so that no time should be lost in evacuating the tympanic contents. In other words, it is absolutely impossible to tell what is going to happen to a bulging drum. Furthermore, it is only the well-to-do who can afford to have unremitting attention paid to their condition, or those in a hospital; and if the intern or the attending physician is too busy to watch these patients carefully, valuable time may be lost. Therefore, while patients with bulging drums may recover by conservative treatment, the end-result may not also be good, for this exudate may cause adhesions, and if it involves the region of the round and oval windows, serious impairment of hearing may ensue. I have tried conservatism, but I feel that prompt action has given more satisfactory results than the

awaiting of the prolongation of the symptoms. The drum may rupture spontaneously, and this is to be avoided, as a sloughed opening is not as desirable as an incised one, although the spontaneous opening may be widened. One must consider that before the opening is sloughed open, damage is being done to the interior of the tympanum.

EDWARD L. MEIERHOF, M.D., New York.

PRIORITY IN SUGGESTING TRANSILLUMINATION FOR FOREIGN BODIES

To the Editor:—In THE JOURNAL, Sept. 6, 1919, p. 766, there was published a clinical note on "The Removal of Foreign Bodies from the Tissues by the Use of Transillumination," by A. G. Bettman, M.D., Portland, Ore. The method is not new. I described it in the *Medical Record*, Nov. 4, 1911, under the heading: "Transillumination in Locating Foreign Bodies in the Extremities."

MORRIS H. KAHN, M.D., New York.

REVERSAL OF THE LYMPH CIRCULATION IN SURGICAL DRAINAGE

To the Editor:—Exception has been taken by several writers to the expression "reversal of the lymph circulation" used in my article on "Surgical Drainage from a Biologic Point of View" (THE JOURNAL, Jan. 17, 1920, p. 159). The term was used to describe what appears to be the chief biologic process by which drainage acts beneficially in solid soft tissue and in endothelial cavities.

The words "reversal of the lymph circulation" may not have been happily chosen, but I know no other phrase that would be quite as satisfactory. I fully appreciate the impossibility of any real reversal of blood circulation, and in other communications I have attempted to demonstrate that a vein and its contributing branches would not function as an artery when an arterial current is turned into the vein (Horsley and Whitehead: THE JOURNAL, March 13, 1915, p. 873; Horsley: *Annals of Surgery*, March, 1916, p. 277). It was at one time, however, rather generally held that the blood circulation could be reversed in this manner.

The phrase "reversal of the lymph circulation" is not intended to mean reversal in the physiologic sense, that is, change in the direction of the lymph current within its normal channels. Surgical drainage is not a physiologic but a pathologic process. Lymph or serum is continually poured around an offending foreign body until the foreign body is removed. This lymph comes partly from the injured lymph channels and lymph spaces in the tissues and partly through the uninjured walls of the lymph channels, which become more permeable with the hyperemia that is present when surgical drainage is necessary.

These are facts that are largely self evident. The moot point is whether this process can be called reversal of the lymph circulation. This phrase was used because it seems to me that the current of lymph or serum continually poured out to the surface of the skin for days or weeks constitutes in a sense a circulation of lymph. This current, if it rises to the surface of the body and appears on the skin or mucous membrane, is not in the direction of any known normal lymph current and probably is a reversal, or at least a deflection, of the direction of the adjoining normal lymph currents. Then, too, this phrase seems to emphasize a phenomenon that many surgeons apparently ignore. The phrase "outpouring of lymph" occurred to me, but this suggests an almost instantaneous process, or at least one that covers a very short space of time.

It may also be objected that "lymph" is used in rather a loose sense. I have employed it as indicating the thin, clear fluid that is found in the lymph channels and spaces of the

body and that infiltrates the tissues in edema. In order to describe the phenomena of surgical drainage, it appears to be necessary to use the words lymph or serum to indicate such fluids.

J. SHELTON HORSLEY, M.D., Richmond, Va.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DECOLORIZATION OF HAINES' SOLUTION—DIFFERENTIATION OF PUS CELLS FROM LEUKOCYTES IN URINE

To the Editor:—1. Will you kindly tell me what it is in the urine that takes all of the blue color out of a Haines test solution—that is, makes it clear like water. Two weeks ago the urine of a woman was heavily loaded with sugar. Under diet there is now no sugar, but 10 drops in a dram of Haines' solution takes out all the color, as stated.

2. In a report sent out by an insurance company to its policy holders on the microscopic examination of urine, there are two blank spaces. One space is for leukocytes, and the other for pus cells. The report may read "leukocytes none," "pus cells few." I wish you would tell me how the different kinds of white cells can be made out in a urinary examination?

JAMES L. TRACY, M.D., Toledo, Ohio.

ANSWER.—1. In the use of Haines' or other copper test solutions, the presence of sugar is denoted by the formation of a yellow or reddish precipitate of cuprous oxid. The extent of the precipitate is partly dependent on the amount of sugar in the urine used. In some cases, in which the sugar is low in amount, only slight precipitation is evident; but some precipitation of the cuprous oxid should be noted in the presence of sugar. Mere decolorization of the copper solution is in no way indicative of the presence of sugar. This decolorization is observed with urines showing an excess of creatinin, uric acid, conjugated glycuronates, and certain preservatives. However, if these substances are present in large amounts, typical precipitation of the cuprous oxid may occur. A direct answer, therefore, to the first question would be that the decolorization of the Haines' solution was due to excess of creatinin, or uric acid, or to conjugated glycuronates if the patient has been taking some drug which is excreted in the urine as a conjugated glycuronate.

2. Concerning the differentiation of pus cells from leukocytes in a urinary sediment, it is to be said that this rests largely on the number and appearance of the cells in question. Practically every specimen of urine shows occasional scattered white cells, but these are not to be dignified by the term "pus cells" unless present in appreciable numbers, many of which are grouped in clumps. The true leukocytes show, when stained, a well-defined nucleus and granulations, while the pus cell exhibits an irregular, granular, degenerated nucleus owing to the lysis that is occurring in the cell. As a rule, a few cells in the sediment are reported as leukocytes rather than as pus cells, being given the latter name only when present in number. As the usual pus cell corresponds to the polymorphonuclear leukocyte, staining methods must be resorted to in order to bring out the character of the nucleus and the granular bodies, both of which characteristics are not clearly shown in pus cells, as stated above. In the usual run of urinary examinations this procedure is not followed, as the number and grouping of the white cells is ordinarily sufficient to permit a diagnosis.

STERILIZATION OF CYSTOSCOPES AND URETERAL CATHETERS

To the Editor:—Kindly send formula for the sterilization of cystoscopes and ureteral catheters. A. H. WINKEL, Three Forks, Mont.

ANSWER.—Although instruments composed entirely of metal, or of both metal and glass, or of soft rubber can be sterilized without injury by boiling for from one to three minutes in water or better a 2 per cent. solution of sodium carbonate to prevent tarnishing, preference, in the case of cystoscopes is given to immersing the instrument before use in 5 per cent. phenol solution for from ten to fifteen minutes. Formaldehyd gas is also used but unless whatever is exposed to its action is left in the open for a little while before use, irritation is likely to result with unpleasant consequences to the patient; therefore, the phenol solution is given preference. Ureteral catheters may be boiled unless made of woven fabric in which case they, too, should be immersed in the phenol solution.

COOPERATION OF MEDICAL AND NURSING ORGANIZATIONS FOR THE SOLUTION OF NURSING PROBLEMS

The American Conference on Hospital Service at its meeting in Chicago, March 2, 1920, appointed a committee of seven, each representing a medical or nurse organization, to investigate causes of the shortage of nurses and to offer constructive criticism of present methods of training nurses. Physicians and nurses are asked to give the committee the benefit of their answers or opinions on any or all of the following questions:

(1) What is your opinion of the value of the three-year course for nurses connected with hospitals; the two-year course for nurses connected with hospitals; the high school

prenursing courses; the Red Cross extension courses; short courses and correspondence nursing courses?

(2) Are the principles laid down in the nursing education in these courses right or wrong? If right, why does not present nursing education adequately meet the nursing need? If wrong, how should the training of nurses be made right?

(3) What use are the graduates of these various schools making of their training?

(4) What misuse are the graduates of these schools making of their training?

(5) What, if any, is the nurse wastage during training?

(6) What, if any, is the nurse wastage after finishing the course?

(7) What are some of the reasons for the shortage of nurses today?

(8) What suggestions can be made as to changes in the training which will make it efficient and yet not lower the nursing standard?

Replies should be sent to Louise M. Powell, Supt. School of Nursing, University Hospitals, Minneapolis, Minnesota. The answers will be classified and made a part of the committee's report to the American Conference on Hospital Service at its meeting in Montreal in October.

Wisconsin January Examination

Dr. John M. Dodd, secretary, Wisconsin State Board of Medical Examiners, reports the oral, written and practical examination held at Madison, Jan. 14-16, 1920. The examination covered 14 subjects and included 100 questions. An average of 75 per cent. was required to pass. Of the 14 candidates examined, 13 passed and 1 failed. Six candidates, including 1 osteopath, were licensed by reciprocity. Twelve candidates were licensed by virtue of a commission in the Medical Corps. The following colleges were represented:

New Hampshire March Examination

Dr. Charles Duncan, secretary of the New Hampshire State Medical Board, reports the written examination held at Concord, March 11-12, 1920. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. One candidate was examined and passed. Ten candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Columbia University	(1917)	80.6

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Hahnemann Med. Coll. and Hosp., Chicago	(1896)	Mass.

University of Vermont	(1911)	Vermont

Book Notices

PRACTICAL ORTHODONTIA. By Martin Dewey, D.D.S., M.D. Fourth edition. Cloth. Price, \$5.50. Pp. 532, with illustrations. St. Louis: C. V. Mosby Company, 1919.

The first edition of this work appeared in 1914. The present—the fourth edition—presents a revision and considerable enlargement of the third edition. The additions consist largely in the description of additional forms of appliances and their use. The work is avowedly devoted to the idea of multiplicity of forms of appliances, rather than to the idea of standardization and the mastery of the most efficient instrument. The attempt is made to describe all forms of appliances and their application, with critical analysis of their applicability. The book will be of special interest to the general practitioner who is doing some work in this field.

MANUAL OF SURGERY (ROSE AND CARLESS) FOR STUDENTS AND PRACTITIONERS. By Albert Carless, C.B.E., M.B., M.S. Colonel (Temp.), A. M. S. Tenth edition. Cloth. Price, \$8. Pp. 1558. New York: William Wood & Co., 1920.

Five years have elapsed since the appearance of the ninth edition of this book. As with most standard textbooks now being issued, extensive revisions have been made, based on developments of the surgery of the war. Carless points out that the problem of determining the ultimate value in civilian work of the many methods introduced as war time emergencies has not been an easy one. There can be little question that some of these methods will pass away. He has thought best, however, to include in the present edition virtually all methods recently introduced. This, the author points out, has somewhat enlarged the size of the book, and thereby its price. The ninth edition contained 1,408 pages, while the tenth edition contains 1,558 and includes a large roentgenographic supplement. The book has however changed somewhat in form, the ninth edition having a page 9 by 6, the tenth edition, 8¾ by 5¾. New work has been added in three chief directions: treatment of infected wounds; compound fractures, and in making good the defects of war wounds.

PHYSICAL RECONSTRUCTION AND ORTHOPEDICS. By Harry Eaton Stewart, M.D., Captain, Medical Corps, U. S. Army, Division of Orthopedics. Cloth. Price, \$3.75. Pp. 275, with 64 illustrations. New York: Paul B. Hoeber, 1920.

This is a condensed manual with numerous well chosen illustrations designed to give expression to the author's ideas on these related subjects as developed from his experience in the gymnasium and in reconstruction work in the army. It tends naturally to the emphasis of massage, exercise and other forms of physiotherapy, and will be the more acceptable to those engaged in these and similar lines of work. Considerably more than half of the volume is devoted to orthopedics, briefly reviewing the usual orthopedic subjects and including fractures and dislocations of the long bones. A little more than one-half page is devoted to club-foot, and less than one-half page to congenital dislocation of the hip. Included in the congenital defects are rickets and coxa vara. From the orthopedic standpoint it is difficult to find just the yearning vacancy this volume will fill, as in its briefness it can only suggest treatment which no trained man needs and no untrained man can safely follow.

PRÉCIS DE BIOCHÉMIE. Par E. Lambling, Professeur à la Faculté de Médecine de l'Université de Lille. Second edition. Paper, Price, 15 francs net. Pp. 708. Paris: Masson et Cie, 1919.

This edition of Lambling's Biochemistry has been entirely rewritten, and has been brought fairly well up to date. The new discussions include, among other points, a rather complete outline of the colloidal state and its influence on physiologic processes; chemical specificity of the tissues; formation of biliary calculi; the comparative alimentary value of proteins and the special nutritive rôle of the amino-acids; glycolysis; the metabolism of fats; the physiologic acidity of the urine; the importance of vitamins, and nitrogen metabolism during growth. The subject-matter of the text is writ-

ten in a clear and concise style; and the discussions, although somewhat limited, are, nevertheless, adequate for the purpose. While little is presented that is not found in our own American textbooks on this subject, this work of Lambling should be found of value as collateral reading, especially for those who wish to obtain a working reading knowledge of French, as well as a concise discussion of the many points involved in the subject of biochemistry.

THE MODEL T FORD CAR, TRUCK AND TRACTOR CONVERSION SETS; ALSO FORDSON FARM TRACTOR AND F. A. LIGHTING AND STARTING SYSTEM CONSTRUCTION, OPERATION AND REPAIR. The Most Complete, Practical Treatise Explaining the Operating Principles of all Parts of the Ford Automobile, with Instructions for Driving, Maintenance and Repairing; also Complete Instructions on Fordson Tractor. By Victor W. Page, M.S.A.E. Cloth. Price, \$1.50. Pp. 410, with 153 illustrations. New York: The Norman W. Henley Publishing Company, 1920.

This is a book for Ford owners: not for Packard, Winton, Pierce-Arrow or Marmon owners, but solely for Ford owners. Just why the flivver should have a book devoted entirely to it we do not know. Is it possible that it is because Hunka Tin is of more importance than all other motor cars? Or is it because it needs more attention than others? We hesitate to say. Be that as it may, here is a book of more than 400 pages devoted to practical information regarding this "universal car," and it should prove of practical value to those of us who are fortunate enough to own one.

Medicolegal

Implication from Collection of Hospital Fees

(*Courchesne v. Brown (Texas)*, 216 S. W. R. 674)

The Court of Civil Appeals of Texas, in reversing, for insufficiency of proof, a judgment that was rendered in favor of plaintiff Brown, who sued to recover hospital expenses incurred by him after an attack of appendicitis while he was in defendant Courchesne's employ and had had \$1 a month deducted from his wages as "hospital fees," says that the court found no case which it considered directly in point in which the issues presented here were discussed. In the cases examined, a hospital had already been furnished and was in use at the time of the collection of the hospital fees. Here the defendant had no hospital, and no custom was shown of his having furnished hospital service. The fund collected must be considered a trust fund. No method was shown for executing the trust, and the defendant was charged with the duty of administering it in such manner as would best accomplish the end for which it was accumulated; that is, to provide for the care of the sick employees who should come within the terms of the trust. Evidently the extent of the duty the defendant assumed in collecting the fund was to administer it properly. If the defendant had a hospital, the implication arising from the collection of the fees would be service at the hospital; but, having no hospital, the court thinks it would not necessarily be implied that he would furnish one. It was a matter of allegation and proof. The court thinks that if the defendant was liable for hospital service in the absence of a hospital of his own, or custom of having furnished hospital service, it would be necessary to allege and to prove that the defendant, as trustee, had on hand an unexpended portion of the trust fund which the plaintiff was entitled to have administered by the defendant in the discharge of the hospital services rendered. The defendant assumed no personal liability to the plaintiff beyond that of a proper and faithful administration of the trust fund. While the court thinks that the evidence was rather meager and unsatisfactory as to the purpose for which the funds were collected, beyond that it was for hospital fees, the court thinks that the evidence was sufficient to go to the jury on that issue. "Hospital fees" might mean that it was to provide a hospital, and it might mean that it was to be administered only in case of sickness. The court thinks, however, that, in the absence of a hospital owned or

Irresistible Impulse Alone Not Defense to Crime

(*State v. Carrigan* (N. J.), 108 Atl. R. 315)

The Supreme Court of New Jersey, in affirming a conviction of murder in the first degree, holds that the trial judge did not err in refusing to charge the jury that if they found that there existed in the defendant's mind an irresistible impulse to take the life of the deceased, and the shooting took place under the influence of such an impulse, the defendant could not be convicted of murder in the first degree. The court says that the fundamental proposition embodied in the instruction was that an act done under an irresistible impulse cannot as a matter of law be wilful, deliberate and premeditated, within the meaning of the New Jersey statute defining murder in the first degree. The proposition is untenable. Conceding for the moment that the law recognizes the existence of an impulse which is irresistible as an element to be considered in determining the grade of a criminal homicide, the question in every case in which that element exists is whether the act was wilful, deliberate and premeditated, notwithstanding that its perpetration was the result of such impulse; and that question is clearly one of fact to be settled by the jury, for it involves the mental operations of the defendant, and they are not to be resolved by the arbitrary application of legal rules, but by a consideration of the facts and circumstances of the case which throw light thereon. The court thinks, also, that the requested instruction was properly refused on a broader ground. The court considers to be unsound the suggestion that the law recognizes a form of insanity in which the faculties are so affected that the person suffering from it, although he perceives and appreciates the moral quality of his acts, is unable to control them, and is urged by some mysterious pressure, which he cannot resist, to their commission. It may be that such a mental condition is recognized by medical or scientific authority; but the doctrine that a criminal act may be excused or mitigated on the notion of an irresistible impulse to commit it, when the offender has the mental capacity to appreciate his legal and moral duty in respect to it, has no place in the law.

State Antinarcotic Law Not in Conflict with Federal Act

(*State ex rel. Whipple v. Martinson, Sheriff* (Minn.), 174 N. W. R. 823)

The Supreme Court of Minnesota holds, in this habeas corpus case, that Chapter 260 of the laws of that state of 1915, restricting the manufacture, sale and dispensing of certain habit-forming narcotic drugs, as involved in the case of *State v. Whipple*, 173 N. W. R. 801, recently decided, does not conflict with the act of Congress known as the Harrison Narcotic Law, and that the judgment of conviction therein, of a violation of this chapter by Whipple, a physician, was not unlawful as violative of the paramount legislative power of the federal Congress or otherwise. The court says that, conceding, without considering or deciding the point, which it thinks of doubtful merit, that the right of legislation on the subject in hand is paramount in the federal Congress, and that the state statute is void so far as it conflicts with the act of Congress, the court is unable after careful examination and comparison of the two statutes to discover any conflict in the respect claimed.

AMERICAN ASSOCIATION OF ANESTHETISTS

Eighth Annual Meeting, held at New Orleans, April 26-27, 1920

DR. ALBERT H. MILLER, Providence, R. I., in the Chair.

Some Anesthetic Relations

DR. A. H. MILLER, Providence, R. I.: The degree of danger attending the use of anesthetics is still unknown. The more postoperative deaths are studied the more evident it becomes that a considerable number may be traced directly or indirectly to the effects of anesthesia. The teaching of the science and practice of anesthesia in the medical schools and clinical hospitals has been neglected. In hospitals the preoperative examination of patients, the choice and the administration of anesthetics are all generally neglected. In many clinics only one agent and one method of administration is available and must be used regardless of the nature of the operation or the condition of the patient. In the larger institutions the present conditions may be remedied through the appointment of full-time, resident anesthetists. They should supervise the preliminary examination of the patients, consult with the surgical staff in regard to the choice of anesthetic agents and methods of administration, supervise difficult cases, instruct juniors in practical anesthesia and be responsible for the condition of anesthetic apparatus. While the anesthetists are trying to foster the literature of anesthesia, the larger medical and surgical journals are ignoring the subject. To remedy existing conditions it would seem advisable to encourage joint sessions of anesthetic societies with surgical associations with programs devoted to symposiums on pertinent subjects of common interest. A committee on statistics should be appointed to collect all available data and encourage private reports on fatalities. There should also be committees on instruction in medical schools and the standardization of anesthetic methods in hospitals.

Accidents During Anesthesia

DR. R. M. WATERS, Sioux City, Iowa: Anesthetic mortality is much higher than usually supposed. Recently, Dr. Stewart, of Cincinnati, compiled statistics of 10,700 operations for removal of tonsils and adenoids and found that twenty deaths had occurred in the series. The five deaths occurring under anesthesia in my own experience have taught me that every possible precaution must be taken in cases in which complicating disease has affected the heart muscle. Such patients under ordinary methods of anesthesia are apt to die unexpectedly. Patients may die of intense fear, and worry about and dread of the anesthetic may delay digestion so that vomiting under anesthesia may cause death

by the inspiration of vomitus into the trachea. In one instance a piece of meat lodged in the glottic entrance and caused death. The possibility of respiratory obstruction from inhaled vomitus is increased in the semireclining position and diminished in the forward inclined sitting posture or in the horizontal position with the head low. Obviously also more fatalities are bound to occur from accidents under anesthesia in emergency than in properly prepared patients.

Anesthesia in Experimental Surgery

F. C. MANN, M.D., Rochester, Minn.: Ether is the best anesthetic for use in most laboratory work. The reactions of the various species of experimental animals seem to be more uniform to ether than to any other general anesthetic. We have found the McGrath method of auto-inhalation, induced by preliminary etherization in an air-tight cabinet, very satisfactory for all purposes. The ether container may be the simple can with regulatory valves or more complicated devices such as the Adson-Little insufflation machine or the Connell anesthesiometer. Smaller species of animals such as the guinea-pig, rabbit and cat are best anesthetized by the old-fashioned cone method, following preliminary etherization in a bell-jar. The goat is very susceptible to excessive salivary secretion under ether and unless given preliminary morphin-atropin and carefully anesthetized by intubation may drown in its own secretion.

Induction of Anesthesia and Analgesia by Oral Administration of Various Drugs

DR. A. FICKLEN, New Orleans: The problem of dressing extensive wounds has always presented difficulties to the surgeons on account of the pain inflicted on the patient. I use the following formula: Chloroform, 5 c.c., ether and liquid petrolatum, each 20 c.c. Recently I have found oral analgesia serviceable in the dressing of painful wounds, setting of fractures, skin grafting and other painful procedures in hospital practice. I have also collected seven cases in which the ether-chloroform-petrolatum mixture was used in obstetrics. The patients showed varying degrees of analgesia and light anesthesia. The mixture did not seem to diminish the contractions of the uterus even when the patients were asleep. Apparently there were no ill effects on the child. In one case tests showed the analgesia sufficient for repairing lacerations. Syrup of yerba santa, in I dram doses, helps to disguise the burning taste of the mixture to a certain extent.

Experimental Studies on Effects of Anesthetics in Shock

DR. McKEEN CATTELL, Cambridge, Mass.: In the normal animal, ether, rapidly administered, causes a moderate fall in blood pressure, followed immediately by a recovery, so that by the time a degree of anesthetization is reached sufficient to cause a disappearance of the eye reflex, the pressure is normal. In shock the animal becomes very sensitive to ether, the same degree of anesthesia produced under exactly similar conditions resulting in a marked drop in blood pressure. An increased sensitiveness to ether is brought about by any circumstances which tend to depress the general condition of the animal, such as low blood pressure, hemorrhage, severe operation or the injection of acid into the circulation. In a shocked animal, sensitive to ether, nitrous oxid and oxygen may be given in the most favorable proportions so as to produce the same degree of anesthesia produced by ether without causing a fall in blood pressure. Experiments on the heart volume in intact cats and on contractions of the isolated turtle heart, together with deductions from blood pressure show that ether from the very beginning of its administration results in a depression of the heart and a decrease in its output, which is sufficient to account for the fall in pressure in both the normal and the shocked animal. Large doses of epinephrin injected intravenously in shocked animals usually results in the disappearance of the sensitiveness to ether for a period of an hour or more. The evidence indicates that epinephrin acts on the heart in a manner which antagonizes the effects of ether. Pituitary extract does not influence the pressure drop produced by ether in the shocked animal. Determinations of leg volume

with a plethysmograph, perfusion experiments and results obtained from the injection of ether directly into the circulation, together with the form of the blood pressure curves, indicate that ether causes a contraction of the peripheral vessels in the normal animal. This constriction is caused by (a) a direct stimulation of the vasomotor center and (b) by a reflex to the fall in pressure resulting from depression of the heart. In shock no evidence of a vasoconstriction produced by ether was obtained, and pressor effects from asphyxia or sensory nerve stimulation become less or are entirely absent. The cause of the greater depressing influence of ether on the blood pressure in shock is a disturbance of the vasomotor system. The usual compensatory constriction no longer occurs to offset the decreased output of the heart, so that there is no recovery of the blood pressure during the inhalation of ether, but instead the pressure continues to fall.

Advances in Pure Nitrous Oxid-Oxygen Anesthesia

DR. E. I. McKESON, Toledo, Ohio: Primary saturation of the patient with nitrous oxid fails in some cases to produce sufficient relaxation for certain operations. Nitrous oxid produces muscular relaxation when it is sufficiently concentrated in the tissues and associated with enough oxygen to prevent anoxemic rigidity. High concentration of this gas in the tissue is required to displace the nonanesthetic diluting gases. Secondary saturation, following momentary deoxygenation, intensifies nitrous oxid anesthesia and produces sufficient relaxation for any operation. Secondary saturation is readily lost by subsequent errors in the mixture administered, leaks of air into the apparatus or the patients' air passages and probably by absorption of air through the abdominal cavity and skin requiring occasional resaturation in some cases. Its successful and safe employment depends on an apparatus capable of inflating the lungs with oxygen should the patient be crowded, intentionally or accidentally into spastic apnea. It depends also on an accurate interpretation of the signs of anesthesia, but disregarding the presence or absence of cyanosis as an anesthetic sign. Secondary saturation is not followed by postanesthetic sequels which are detrimental or which may be attributed to its use. It is safer for the patient than an ether sequence or combined gas-oxygen-ether and convalescence is better when even the small amount of combined ether is avoided.

Open Method of Nitrous Oxid-Oxygen Anesthesia

DR. JAMES T. GWATHMEY, New York: This method is offered as a substitute for the open-drop or any other method of etherization and also as an aid in anesthetizing certain patients to whom the closed method seems a burden. A mask twice the size of the usual drop-ether mask is used and is sufficiently large to hold a full inspiration of an adult. The mask is covered with several layers of gauze and scented with essence of orange or oil of bitter orange peel. The anesthetic is started with three holes of nitrous oxid and one of oxygen and in from 10 to 15 seconds the anesthetic valve is turned just enough to have the gases barely bubble through and from this on it is very gradually increased until there is a slight bead on top of the liquid. In one minute or one minute and a half the patient will be unconscious but not anesthetized. The technic from this on will vary with the substance that is to be used in connection with the gas-oxygen. Toward the close of the operation the patient is oxygenated for a short time before leaving the table.

Relaxants in Nitrous Oxid-Oxygen Anesthesia

DR. ANSEL M. CAINE, New Orleans: Nitrous oxid-oxygen would be the anesthetic of choice in all hazardous risks were it possible to secure adequate relaxation. Proper manipulation of the oxygen supply, slight positive pressure, warming the gases and preliminary medication as well as concomitant local analgesia all help in securing the desired degree of relaxation. In a certain number of cases, however, the addition of ether, chloroform or other anesthetic will be required. I have found chloroform a safe, efficient and pleasant adjunct to gas-oxygen-anesthesia for relaxation.

*Congenital Absence of One Lung. C. S. Levy, Baltimore.—p. 237.

*Secondary Meningitis Treated by Intraspinal Administration of Autogenous Serum. Report of Case. T. M. Sanders, New York. —p. 246.

Colloidal Gold Reaction with Cerebrospinal Fluid. E. Kellert, Albany. —p. 257.

*Preparation of Stable Vitamin Product and Its Value in Nutrition. H. E. Dubin and M. J. Lewi, New York.—p. 264.

Brachial Birth Palsy.—Thomas maintains that obstetric or brachial birth palsy represents only one phase of a much larger shoulder joint problem. Almost, if not all, shoulder joint injuries are associated with a brachial paralysis, palsy or weakness of varying degree and duration. Very rarely will an actual nerve rupture be associated with the paralysis. Thomas doubts that sufficient traction on the head at birth to rupture the brachial plexus has ever been applied in a successful delivery.

Multiple Gummas of Tendons.—A case of multiple and symmetrical gummas of the tendons is described by Goodman and Young which clinically closely resemble the tumors of juxta-articular nodules. The suggestive history, positive Wassermann, and histology of one of the lesions puts the diagnosis of multiple syphilitic gummas of the tendons on a sound basis.

Congenital Absence of One Lung.—Twenty-one cases of congenital absence of one lung are reported in the literature. There are, in addition to these reports, four cases in the literature where a possible rudimentary lung has been found covering an imperfectly developed primary bronchus. An additional case is recorded by Levy, one of congenital absence of one lung in a patient who was treated for the urinary incontinence of tabes dorsalis. The patient was 49 years old. This is the first case of congenital absence of one lung in almost 6,000 necropsies performed in the pathologic department of the Johns Hopkins Hospital.

Autogenous Serum in Meningitis.—Sanders recommends the use of autogenous serum injected into the subarachnoid space in cases of secondary meningitis when there is no efficient specific immune serum.

Stable Vitamin Product.—Dubin and Lewi prepared a stable vitamin product, designated, "V." An analysis shows the chief components to be calcium, expressed as calcium oxid, 10 per cent.; phosphorus, 15 per cent.; nitrogen, 3.5 per cent.; fat, 2.5 per cent.; iron, 0.3 per cent.; silicates 5.6 per cent.; moisture, 10 per cent. The remainder goes to make up the rest of the phytin molecule—the main constituent of the product—which is a double calcium and magnesium compound of inositol phosphoric acid. Owing to the method of preparation and to the results of experiments with normal and polyneuritic pigeons, normal and scorbutic guinea-pigs and finally with children presenting evidence of malnutrition, marasmus and rickets—a marked acceleration in the rate of growth having been obtained, particularly in the children—it is established that the product contains antineuritic, antiscorbutic and antirachitic vitamins. It is felt by the authors that until such time as the vitamins shall have been isolated and their chemical composition determined, their vitamin preparation is an admirable substitute and may be used with confidence in such a manner as described by Voegtlin. It is

not intended as a substitute for any method of treatment nor is it meant to be used in infant feeding only. Rather is it intended to be a valuable aid whenever its use is indicated. At the same time, it should not be lost sight of that the diet must contain sufficient protein, fats, carbohydrates and mineral salts and that the caloric value must be adequate for the needs of the individual.

*Lymphosarcoma and Syphilis. O. Berghausen, Cincinnati.—p. 317.

*Syphilis of Prostate. L. Thompson, Hot Springs, Ark.—p. 323.

*Syphilis in Pregnancy and Labor. E. L. Cornell and A. W. Stillians, Chicago.—p. 342.

Ocular Syphilis and Its Treatment: Report of Cases. W. J. Young, Louisville.—p. 346.

Standardization in Treatment of Syphilis. B. C. Corbus, Chicago.—p. 353.

Intraspinal Injections in Neurosyphilis.—This paper is based on an analysis of 210 cases of neurosyphilis and many important points are discussed and illustrated by reports of cases. One of the points emphasized by Scott and Pearson is that intraspinal injections are not only of use in the treatment of neurosyphilis but are also an aid to diagnosis. The introduction of a small dose of arsphenamized serum into the spinal canal sets up a reaction analogous to the Herxheimer reaction in that, if syphilitic infection is present, the liberated toxins from the destroyed *Spirochaeta pallida* increase the inflammatory reaction and so cause the positivity of the fluid to increase. By this reaction, if a case is suspected from clinical indications to be neurosyphilis but is serologically negative, an injection of a small dose of arsphenamized serum may render the fluid positive.

Wassermann Control in Treatment of Syphilis.—Sargent's experience with inherited syphilis treated by both arsphenamin and mercury has been limited to about a dozen cases. It has been sufficient, however, to warrant the conclusion that it is worth while attempting to cure them. From these few cases it has seemed that they react to treatment in about the same way as do adults with acquired syphilis of many years' duration. In Sargent's opinion the Wassermann offers an excellent control in the treatment of syphilis, but only, however, when taken in consideration with the physical findings and with the past history of the patient, including the amount of his treatment. Wassermann positive primary syphilis cannot be cured by a few injections of arsphenamin and a few months of mercury, but when treated intensively and over a long period, offers an excellent prognosis. There seem good grounds for the belief that many cases of secondary and tertiary syphilis, even of years' duration, when treated intensively both with arsenic and mercury for one, two or three years can be rendered Wassermann negative and apparently cured. In at least some cases of early tabes it is possible to render both the blood and spinal fluid negative to the various clinical tests.

Id.—Enough time has elapsed since the introduction of the Wassermann reaction and comparison of its readings with associated clinical aspects, Oettinger says, to prove that this test is not a reliable guide for treatment.

Lymphosarcoma and Syphilis.—Two cases of association of these two diseases are reported by Berghausen. In the first case, the general enlargement of the lymph glands was marked, but the marked enlargement of the spleen and abdominal lymph glands made the clinical diagnosis of lymphosarcoma rather easy. In the second patient the enlargement of the peripheral glands was so marked, involv-

ing chiefly the glands of the neck at first, that the probable diagnosis of Hodgkin's disease was made. In both instances there was no question as to coexistence of syphilis; the patients admitted specific infection and the blood Wassermann reaction was strongly positive to different antigens. Antispecific treatment was only of temporary benefit, proving of some value in the second patient, causing a decrease in the size of the glands of the neck but not preventing the gradual invasion of the entire lymphatic system.

Syphilis of Prostate.—Only twenty-four cases purporting to be syphilis of the prostate have been recorded in the literature, and of these only twelve, or 50 per cent., are accepted as authentic. Thompson adds one case in which the diagnosis is said to be indisputable.

Syphilis in Pregnancy.—Of sixty-nine pregnant women tested by Cornell and Stillians for syphilis, two gave a strongly positive and one a slightly positive reaction. Eighteen out of the sixty-nine cases gave a history of abortion or still-birth aside from one case which was syphilitic. This is a percentage of 26. Of the three syphilitics, one had aborted.

Relation of Creatinin Metabolism to Arthritis.—Determinations of the creatin, creatinin and nonprotein nitrogen of the blood and urine of forty cases of arthritis and nine normal controls are presented by Pemberton and Buckman. About one half of the cases of arthritis showed an abnormally high value for blood creatin. A certain number of patients showed a decline in blood creatin simultaneous with clinical improvement. Only three of the cases showed creatinuria. Only two cases showed an abnormal elevation of nonprotein nitrogen of the blood. Figures are presented which suggest that a considerable amount of creatin is occluded in the precipitation of the proteins of whole blood and plasma.

Restricted Carbohydrate Diet in Arthritis.—The value of the treatment of these arthritis patients by a restricted carbohydrate diet finds additional support in the studies on blood sugar, revealing a difficulty in the utilization of carbohydrate. It seems clear that success following this measure depends on catering to a weakened function of which the lowered sugar tolerance is one evidence. Treatment along this line has undoubted application in appropriate cases of chronic arthritis. Pemberton urges that the several measures of value in arthritis should be combined in their application more frequently. The tendency to focus on one measure often results in failure where the subsequent coincident use of several measures results in benefit.

Hyperglycemia Following Removal of Pancreas.—Complete removal of the pancreas in Delatour's dogs produced a permanent hyperglycemia, and any part of the pancreas left in the animal after operation later manifested itself by a fall in blood sugar. Epinephrin administered by intravenous injection in normal dogs increased the blood sugar. With the pancreas removed, epinephrin produced very little, if any, change in the blood sugar. Under this condition, as a possible explanation, sugar is passing freely into the circulation unburnt, and therefore the epinephrin can have very little further effect in increasing the blood sugar by inhibiting sugar metabolism. Delatour regards it as reasonable to believe that the pancreas produces some substances which favor the metabolism of the sugars in the tissues, as sugar injected intravenously is not handled as readily in the depancreatized animal as in the normal dog.

Rôle of Lipoids in Blood.—It is Henes' belief that the lipoids of the blood play a rôle analogous to an antitoxin, and are intimately associated in immunologic processes. The lipoids seem to act as a protection to the animal organism, and are known to counteract certain poisonous substances. Recent literature abounds in substantiation of the belief, that cholesterol plays some protective rôle in the animal organism. The prognostic value of the measure of cholesterinemia in chronic nephritis becomes of greater interest and importance because of these facts.

Unusual Mechanism of Auricular Pacemaker.—Three clinical examples of unusual mechanism of the auricular pacemaker are reported by White: (1) Paroxysmal tachycardia arising in or very near the sino-auricular node and not showing an absolutely abrupt onset or offset. (2) Migration of the pacemaker in the sino-auricular node, two foci alternating action in one case. (3) Sudden halving of the auricular rate (sino-auricular block) after exercise.

Spirillar Bronchitis.—It would appear from Nolf's study of eleven cases that spirillar bronchopneumonia is a malady of temperate climes, and that it has probably been confounded up to the present time with pulmonary gangrene consecutive to acute or chronic affections of the respiratory tract. Its micro-organism is probably a common inhabitant of the upper respiratory passages, particularly of the mouth and pharynx.

Influenza Epidemic.—A study of the census statistics for the larger cities of the United States as a whole, made by Winslow and Rogers, showed a very definite relation between the severity of the 1918 epidemic and both the pneumonia death rate and the total death rate for the sixteen years preceding. The relationship is, in general, a geographic one, the Eastern and Southern cities showing high death rates, the Middle Western and Western cities showing low death rates in each case. In the Eastern section the results are attributed to unfavorable economic conditions associated with industrial life and the presence of certain foreign race stocks always characterized by a high death rate.

Grouping of Influenza Bacillus.—Four groups have been identified by Small and Dickson and 70 per cent. of the strains studied fall into two groups. They maintain that the hemophilic organisms (*B. influenzae*) can be grouped by immunologic methods.

Antiseptic and Bactericidal Actions of Chaulmoogra Oil.—This report is concerned exclusively with a study of the antiseptic and bactericidal actions of chaulmoogra oil and its constituents, the identification of the specificity of its bac-

tericidal action for acid-fast bacilli, and an investigation of the presence or absence of this bactericidal substance in cod liver and other oils. Walker and Sweeney state that chaulmoogra oil contains bactericidal substances that are about one hundred times more active than phenol. They are the fatty acids of the chaulmoogric series, chaulmoogric and hydnocarpic acids, and possibly lower isomers of this series. The bactericidal activity is specific for the acid-fast group of bacteria only. The fatty acids of cod liver oil do not possess the specific activity of the chaulmoogric oil series. The authors' experiments do not support the claim of Rogers for sodium morrhuate in the specific therapy of tuberculosis but their findings do supply a scientific basis for the use of chaulmoogra oil and its products in leprosy.

Experimental Streptococcus Empyema.—According to the results obtained by Gay and Stone, experimental streptococcus empyema in rabbits may be prevented by previous immunization with killed, followed by living, cultures of the same strain of streptococcus, but only when repeated vaccinations have been practiced and in a total amount which would seem to preclude the practicability of such a preventive inoculation in human beings, provided the conditions are similar. Attempted vaccine therapy of the localized symptoms has given consistently negative results.

Streptolysin.—Hemolysin production in serum broth by beta hemolytic streptococcus was studied by de Kruif and Ireland. The data gleaned have been used in the synthesis of a new blood agar plate.

Colon-Typhoid Group Bacillus in Furunculosis.—From a pure culture of this organism, Oliver and Schwab made an autogenous vaccine. Following the initial injection of minim (about one-half billion bacilli per cubic centimeter) the patient exhibited marked local and general reaction. As a result of this treatment, the patient was free from boils for almost two years. In the opinion of the authors this suggests a relationship of the bacillus to the disease. The organism and its life history are described in detail.

Hyperchlorhydria Causing Poor Appetite.—Kerley maintains that a common cause of defective appetite in children of the runabout age, or older, is hyperchlorhydria, with the resulting symptoms of variable desire for food, indefinite abdominal pains, flatulency, and acid eructations. The treatment consists of giving alkalies to neutralize the excess of acids, of substituting an easily digestible, nonirritative diet, and of giving due attention to general hygienic measures.

Skin as Index to Health.—Scholtz points out that in many conditions the skin lesion is merely a manifestation of a general disease, therefore the closest cooperation between internist and dermatologist is both essential and of value. Such cooperation would help the dermatologist as much as the clinician, because in the absence of thorough systemic examination many patients receive only symptomatic relief.

Acute Intussusception.—Levy pleads for less haste in adopting radical methods in these cases, especially when they are seen early. In the case reported, he gave an enema of 1 quart of sterile water very slowly with relief of the intussusception. He advises not to elevate the container more than 6 feet.

Delayed Postoperative Hemorrhage After Tonsillectomy.—The tenth night after operation, Hubbard's patient had a profuse hemorrhage from the mouth, her condition prior to that time having been wholly satisfactory.

Transmitting Influenza Through Fleas.—Engelbreth conducted experiments on human beings. Fleas were allowed to bite persons suffering from undoubted influenza, and some with a complicating pneumonia, and, then, these fleas were placed on the skin of normal persons. In one half of the fourteen experiments made the result was negative. The author suggests that, perhaps, the fleas used had not been infected or that the infection in them had run out. Infected fleas died much more quickly than uninfected fleas. In the positive cases, the symptoms were those of a mild influenza, such as occurs for the most part in epidemics of this disease, and without complications, except in one case in which pneumonia developed.

Acute Indigestion.—The cases of death from "acute indigestion" reported by the lay press Robinson says are really not such at all. The cause of death in these cases is primarily an overstrained, weakened heart, already diseased, or a cerebral hemorrhage, a weakened circulation with diseased arteries causing stasis in the vessels of the brain. He regards the use of strophanthus, a hypodermic tablet placed under the tongue, as the best treatment in these cases.

 *Local Paralysis Following Superficial Injuries not Involving Nerve Trunks: Traumatic "Ascending Neuritis" and "Reflex Paralysis." F. M. R. Walshe.—p. 339.

Lethargic Encephalitis.—In the opinion of Buzzard and Greenfield there is no reason to suppose that lethargic encephalitis is a new disease; endemic cases occur from time to time. Cases of patients suffering from symptoms of acute or subacute cerebral disease have been diagnosed as cerebral hemorrhage, and in others a diagnosis has never been properly established. A detailed report is given of twenty cases, and the pathologic findings in five fatal cases are described. The histologic appearances of the brains examined were very varying. But there were certain features common to all cases in the early stages. They are: (1) vascular congestion; (2) evidence of toxic degeneration of the nerve cells and neurophagy; (3) proliferation of the mesoblastic cells of the vessel walls, and infiltration of the nervous tissue with these cells; (4) small celled infiltration of the Vichow-Robin space and (5) glial proliferation. They are given in the order in which they occur most constantly.

Traumatic Ascending Paralysis.—Four cases are analyzed by Walshe. They show that a trivial injury, not necessarily a wound and not involving a nerve trunk, may produce marked paresis, or paralysis, with wasting of muscles and diminution of their faradic excitability, impairment of the corresponding tendon jerk, subjective and objective sensory changes and vasomotor disturbances. These signs have a definite anatomic topography and correspond to the innervation of a peripheral nerve. The character of the symptoms is that of a localized neuritis (mononeuritis). Though in every instance progressive, there was evidence of continued upward extension in only one case. In every instance, the injury was within the territory innervated by the affected nerve, though not involving its trunk. In two cases the cutaneous endings of the nerve had been directly injured. In one it overlaid these, while in one case it involved both deep and cutaneous afferent endings. Sepsis does not appear to have been an essential factor. It is clear that in these cases there is an organic disturbance of structures anatomically related. They approximate in type to the conditions known as "ascending neuritis," rather than to the muscular reflex affection of acute arthritis and allied lesions. Walshe suggests that a small proportion of Babinski's cases of "reflex nervous disorders" may have been of the same nature.

Dietetic Treatment of Diabetes Mellitus.—In cases uncomplicated by "acidosis" and certain other secondary affections, when the ordinary restriction of carbohydrates in the diet fails promptly to check the glycosuria, Williamson advises complete rest, and for seven days a diet composed of a mixture of casein, cream and water, given every two hours, from 8 a. m. to 10 p. m., without any soiled food. In many cases this diet promptly checked the glycosuria when other treatment had failed. At the end of the seven days a change is gradually made to a suitable solid diet, the amount of carbohydrates which the patient could tolerate being carefully noted. During the war period, in place of casein and cream solution, Williamson often used a diet composed chiefly of eggs and milk, given every two hours for seven days, or a diet chiefly of suitable vegetables and jelly. Both of these are more palatable, and are often useful, but not so frequently successful as the casein and cream solution. At the end of the war period, the casein obtainable was very often unsatisfactory in taste and odor, and Williamson has recently employed, with great success in many cases a mixture and course of treatment, which can be easily carried out. The mixture is a useful substitute for the casein and cream solution. If "acidosis" and other serious complications can be excluded, and if an ordinary diabetic diet, with restriction of carbohydrates, fails to check the glycosuria promptly, then the patient is advised to rest on the sofa for seven days (or for a shorter period) and to make a mixture of eggs, cream and water, prepared as follows: Three eggs are beaten up with 3 ounces of cream and a little water. More water is then added gradually until the mixture measures 4 pints. Of this mixture the patient takes half a pint every two hours, from 8 a. m. to 10 p. m. In addition, he takes coffee or tea at 8 a. m. and 4 p. m., and also beef tea (warm), half a pint at 12 noon, 6 p. m. and 10 p. m. No bread, no meat, and no other foods are taken during this period. In many cases the glycosuria is promptly checked in from four to seven days. This diet is not continued longer than seven days, and is then slowly changed to a solid diet containing only a small amount of carbohydrate food, the amount of bread and other carbohydrates which can be tolerated being carefully noted.

Nephritis with Abdominal Hemorrhage.—A woman presented symptoms which led Blomfield to make a diagnosis of influenza. Her main complaint was pain in the lumbar region. She improved somewhat under treatment but this back pain continued. The urine contained blood and albumin. The temperature was slightly elevated above the normal. Suddenly she had a "collapse" and died. At the necropsy the peritoneal cavity was found filled with blood and blood clots for which no source could be discovered. The heart was hypertrophied and the walls of the left ventricle were much thickened. At the right edge of the liver was a mass the size of the palm of the hand, resembling a blood clot. There was blood behind the peritoneum near the right kidney and petechial spots on the mesentery. There was also blood tracking up behind the peritoneum and into the thorax. Blomfield believes that this was a case of acute nephritis grafted on a chronic condition which caused a hemorrhagic diathesis.

*Blood Transfusion Before Operation in Severe Secondary Anemias. Herbert Williamson.—p. 867.
Medical Problems of Life Assurance. T. D. Lister.—p. 892.

Tartar Emetic in Bilharziasis.—The experience Cawston has gained from watching a series of cases shows that the scalding and vesical pain that these patients complain of may be expected to disappear after the second or third intravenous injection. The patient will probably remark on the disappearance of the blood from the urine within a week or ten days, though hematuria may be prolonged where there is a tendency to papillomatous growths. Degenerating maricidia may be seen within the shells of the eggs shortly after the dose administered has reached a full grain. Blackened eggs may appear after a total of 1¼ grain has been given. Free swimming, dying maricidia are not uncommon in undiluted urine at the end of the two weeks' treatment. A cloudy condition of the urine due to phosphates is common during the second or third week, and readily responds to treatment. The disease is usually cured when the urine has been free from living eggs for a fortnight or three weeks. The presence of many dead eggs and blood cells indicates that further treatment is required. The absence of living eggs for a month indicates that the female parasites are all dead. If the parasites are going to cause mischief again, they are unlikely to take more than a fortnight to three weeks to recover after the treatment has ceased.

Blood Transfusion in Secondary Anemia.—A case of anemia caused by a uterine fibromyoma in which blood transfusion was resorted to, is reported by Williamson. He says that in the future he will do this before operating for fibromyoma so as to diminish the risk of the operation, lessen the liability to thrombosis, and shorten the period of convalescence. He proposes also, when the patient is very anemic, to adopt this procedure in cases of carcinoma of the cervix before performing Wertheim's operation. He suggests further that blood transfusion should be performed before delivery in cases of severe antepartum hemorrhage.

Prognosis in Tuberculosis. F. Kraus.—p. 56.
*Case of Pneumothorax. N. Robertson.—p. 64.

Effect of Occupation on Tuberculosis Incidence.—Collis maintains that the evidence he adduces proves that there is a type of phthisis which causes death in middle age—that time of life when the effect of occupation has had time to make its impress on the human organism; and that industrial life in some way directly promotes its incidence.

Pneumothorax.—The case reported by Robertson is interesting and unusual because the commencement of the disappearance of pneumothorax signs on the right side was coincident with the appearance of air in the subcutaneous tissues on the left side. Simultaneously the pressure symptoms subsided and the temperature fell. The tissues on the left side were quite definitely crepitant to touch exactly as in a case of surgical emphysema.

Treatment of Laryngeal Tuberculosis with Spiess's Gold Solution (ethylene-diamin-canharidin-aurecyanid). E. G. Glover.—p. 126.

Syphilis and Tuberculosis.—The following statements indicate Miranda's agreement with Sergent's results: Syphilis and tuberculosis are very intimately connected. Syphilis provides a soil for tubercle bacillus. If the organism overcomes the initial effects of the association, and if treatment is commenced, the tuberculosis lesion exhibits a tendency to assume a fibrous nature. Mercury, far from being nocive, is the remedy for syphilotuberculosis.

Chronic Dyspepsia in the Gassed. M. Loeper.—p. 217.

Sugar in Cerebrospinal Fluid in Epidemic Encephalitis.—Dopter found 0.85 gm. per liter of the fluid in a young man with symptoms suggesting tuberculous or syphilitic meningitis. This hyperglycorachia, as he calls it, differentiated the case as epidemic encephalitis as the fluid was limpid and the Wassermann test negative. This excessive sugar content is not constant, but it is an aid in differentiation when found.

Syphilis or Epidemic Encephalitis.—Jeanseime comments on the difficulty of distinguishing between these diseases when the encephalitis develops in a syphilitic. Each is liable to entail dissociated paralysis of the cranial nerves, the Argyll Robertson sign, convulsions and apoplectiform coma. He describes an instructive case of the combination.

Antitetanus Serum in Treatment of Lethargic Encephalitis.—There was prompt improvement in Laubie's two cases and in Coquet's case of severe epidemic encephalitis, with stiffness of the neck and contractures, after intraspinal or subcutaneous injection of antitetanus serum. The injection was made the fourth day in one case, and, in all, the symptoms subsided in thirty-six to forty-eight hours afterward.

Index of Renal Excretion of Water and Chlorids.—Pruche gives a formula for determination of what he call the *coefficient hydrochlorurée*. It is determined by comparing the concentration of chlorids in the urine with the dry residue obtained by evaporation of the blood serum.

Management of School Inspection During Epidemics.—Azoulay suggests having separate quarters, where the classes can be held in case of an epidemic, for the children from homes where there is a case of the epidemic disease, when, on account of quarantine measures, as many as ten or fifteen children have to be excluded from attending school. Children who have recovered from the epidemic disease should also attend this separate school for the contagious, until they can present a certificate from some physician to the effect that danger from them is past. He advises offering a premium for the declaration by physician or layman of an acute contagious disease, verified by a third party. Printed circulars should be distributed to parents, and be placarded, dealing with the disease, its prophylaxis and the necessity for collaborating with the public health authorities.

Prophylaxis of Typhus.—Armand-Delille explains that lice are unable to proliferate when for a third at least of each twenty-four hours they are deprived of the warmth of the body. It takes twelve days for the louse to mature, hence if the clothes are ironed on the inside with a hot iron once a week for four or five weeks, this will interrupt the evolution of the different generations as they develop and none will reach the reproduction period. They thus all die off in time although the hot iron does not kill them all, but it destroys enough of the lice and nits for the purpose, even with a single weekly ironing, especially along the seams. He warns further that when different shifts of workmen occupy the same beds, so that they are more or less continually in use, this breeds vermin rapidly, while letting the bedding grow cold for several hours checks the development and reproduction of lice.

*Vaccines in Therapeutics. L. Girard.—p. 297; in Typhoid. H. Méry.—p. 301; in Typhoid. L. Fournier and A. Schwartz.—p. 303; in Dermatology. A. Mauté.—p. 310; in Epidemic Meningitis. L. Girard.—p. 313.

Aphasia and Apraxia.—Laignel-Lavastine summarizes our present knowledge of this subject, and emphasizes the necessity for eight forms of tests, tests for spontaneous speech, for repeated words, reading aloud, spontaneous writing, writing from a copy and writing from dictation, study of comprehension of spoken words, and study of comprehension of printed words. With apraxia the simple reflex and expressive movements must be studied as well as the descriptive and other movements, as he enumerates in detail.

Vaccines in Therapeutics.—Girard describes the technic for the preparation of vaccines, the indications for them in general, and the diseases for which they have been used to date. Méry reviews the experiences with vaccine in prophylaxis and treatment of typhoid, injected subcutaneously, and Fournier and Schwartz describe their experiences with the same given by the mouth. They report a favorable action from this buccal vaccinothrapy in nearly every case, the prompter and more decided, the earlier in the disease this treatment was begun. The fever rapidly subsided and the course of the disease was notably shortened in the favorable cases. They had only eight deaths among their 150 typhoid patients given this treatment, and in this small group of fatal cases the fatal outcome was due to acute myocarditis, perforation of the bowel the second day, acute appendicitis or complicating influenzal pneumonia. The vaccine they use contains about 0.25 gm. of the desiccated bodies of the bacteria from twenty-four hour cultures of typhoid and paratyphoid bacilli.

Mauté reviews his personal experience with vaccine therapy in skin diseases, declaring that his results have been so interesting that they should inspire every physician to try this method in prophylaxis and in treatment. He prefers autovaccines for their infinitely less toxicity, the absence of local reaction, and the painlessness of the injection, and the fact that recurrences are much less frequent. He refers to Danysz' success with an emulsion of germs from the patient's stools, administered by the mouth and subcutaneously, and states that indirect immunity can be realized with ordinary saprophytes in typhoid and in rebellious eczema and pruritus. He has found further that intravenous injection of a staphylococcus vaccine, 20 millions on alternate days for a series of six injections, has a manifest influence on rebellious acne, and yet acne is not a staphylococcus disease. He theorizes to explain its action, and remarks that, in any event, the fact is worth remembering in treatment of such a rebellious affection as acne.

He has also utilized in treatment of erysipelas a water-soluble substance derived from the stools by precipitation with alcohol, after separating out the albumins with heat in an acid solution; it has a pronounced regulating action on the peripheral circulation. The therapeutic rôle of microbial injections, he continues, is thus becoming more and more extensive, and susceptible of numerous clinical applications hitherto undreamed of. He adds that staphylococcus vaccines seem to be the only efficient ones in dermatology; his experience with streptococcus vaccines has been disappointing, especially in recurring erysipelas. The staphylococcus vaccine can be used not only in furunculosis and carbuncle but also for folliculitis and sycosis. When it is important to act quickly, he does not hesitate to inject the vaccine by the vein. He begins with 10 millions; gives 15 millions the next day, and the third day 20 millions, repeating this last dose two days later. After a pause of three days he begins anew, but only with the preventive doses this time. With these doses, he says, the intravenous injection of the staphylococcus vaccine does not cause any general reaction. For the subcutaneous injection he uses doses of from 250 to 500 millions.

*Plague at Constantinople. Idem.—p. 215.

Acute Suprarenal Insufficiency After Arsenic Treatment of Relapsing Fever.—Monziols and Collignon explain the acute suprarenal insufficiency, sometimes observed after injection of neo-arsphenamin in treatment of relapsing fever, as due to the sudden flooding of the organism with the toxic products liberated by the sudden destruction of the spirochetes. The suprarenals are unable to keep up with their task in these circumstances, and acute suprarenal insufficiency is soon manifest. All trouble from this source could be averted, they found, if epinephrin was injected with the neo-arsphenamin. This tided the patient along without harm until his suprarenals could cope with the conditions.

Plague in Constantinople.—Monziols and Collignon review their experiences with forty-four cases of plague at Constantinople in the last quarter of 1919. The mortality was 40 per cent. The bacillus was found in the blood only in 16 per cent. of the twenty-five examined, and it had disappeared from the blood by the sixth to the twelfth day.

Eczema as a Tuberculid. G. Milian.—p. 206.

Influence of Inadequate Treatment on Appearance of Meningeal Syphilis. M. Pinard.—p. 211.

Dermatology and Syphilis in 1920.—Milian regards as established that there are different kinds of *Spirochaeta pallida*, so that the old term "parasymphilis" for tabes and general paresis is correct. The difference between tabes, general paresis and syphilis in general is analogous to the difference between typhoid and paratyphoid. He comments on Hutinel's recent report of cases of latent inherited syphilis roused to active evolution by some intercurrent acute infectious disease. Lesions may flare up in bone, skin or elsewhere, and the syphilitic nature be overlooked unless the physician is on the alert to recognize the unusual aspect of the intercurrent disease under these circumstances.

Generalized Xanthoma.—Two colored plates show the histologic findings in a case of generalized papulous xanthoma in a boy of 9. His entire body was scattered with small polygonal tumors, yellowish or brown, for which no cause could be discovered. They persisted practically unmodified for nearly five years. Then the child died from privations during the German occupation of his town.

Anaphylaxis.—Louste is inclined to accept the physical theory of anaphylaxis rather than Richet's chemical or Friedländer's biologic theory. The physical theory ascribes the anaphylactic shock to processes of precipitation and absorption between colloids. This would explain the similarity of the phenomena observed, regardless of the etiology. It is possible that the chemical theory supplements the physical theory by assuming a chemical action as predisposing to the physical changes. Treatment should aim not only to ward off the cause but at the same time to train the subject to be less susceptible to the cause. A small preliminary dose or injection of peptone or similar substance adapts the organism so that the anaphylactic shock is warded off. Intolerance to quinin can thus be cultivated away by a small preliminary dose before the therapeutic dose of the drug. Sicard has found that the therapeutic dose of an antiserum can be safely injected into the arm when the circulation is completely shut off. In a few minutes the circulation can be restored by removal of the constricting band, this brief delay being sufficient to ward off danger of anaphylaxis from the antiserum. Pagniez has cured patients of intolerance for albumin in the food by having them take 0.5 gm. of peptone regularly before the meal. It is a simple matter

by this means to confer lasting immunity on the patient and relieve him of his annoying or dangerous idiosyncrasy.

*Myoclonic Encephalitis. J. A. Sicard.—p. 213.
The General Reactions of Bone Tissue in Bone Disease. Nathan.—p. 214.

Myoclonic Encephalitis.—Sicard has encountered in less than three months five cases of what he calls myoclonic encephalitis, and says that it must rank beside lethargic encephalitis. General lassitude and intense lancinating pains with mild fever may keep up for a week or ten days; then comes a week or so of the muscular jerkings and twitchings but there is no contracture, no spasms, no chorea nor athetosis, only actual myoclonia. During this stage the neuralgic pains subside and there is no somnolency nor ocular symptoms. Toward the third week there may be a tendency to delirium but the reflexes and the pupils keep normal. The whole course of the disease is from four to eight weeks. In the terminal stage the delirium is constant but the other symptoms subside, and the patient falls into coma and dies or the delirium subsides and he recovers. The disease does not seem to have a destructive action on the nervous system but rather to fasten on it momentarily and impress it, and then pass off. Although the symptoms seem so grave yet they are transient, and if the patient recovers no permanent damage seems to result.

*Vein Urethroplasties. Legueu.—p. 130.

The Diplogenesis versus the Blastomere Theory in Relation to Double Monsters and Dermoid Cysts. E. Chauvin.—p. 132.

Surgical Importance of the Omentum.—Aimes discusses the protection afforded by the omentum in wounds and at operations, and its usefulness as a plastic material, reviewing the literature on the subject. He also analyzes several hundreds of cases of omentopexy on record, remarking in conclusion that this latter operation has some favorable cases to its credit, but on the whole has not fulfilled its promise. It has a high operative and postoperative mortality, and in cases of cirrhosis benefits only the one symptom, the ascites, and not always this.

Catheterization of the Ureter in Anuria from Concretions.

—Thévenot knows of thirty-eight cases on record besides the two he here describes in which catheterization of the ureter put an end to the anuria either by pushing the calculus back into the kidney or by arresting a reflex spasm or by both mechanisms. If saline, glycerin or oil is injected through the catheter, this may induce reflex action causing the expulsion of the calculus. In some of the cases in the literature the anuria recurred later but was conquered in the same way by catheterizing anew. If there is no sign of uremia, this catheterization might be tried up to the fifth day of the anuria, but after this, or with uremia, nephrotomy should be done at once.

Vein Urethroplasties.—Legueu does not agree with those who think that there are too many drawbacks to using a vein to reconstruct the urethra. He reports a fairly successful case and states that in the twenty-three cases on record, an autograft was used in eighteen. The best results were realized with terminal urethroplasties, as this gives only one zone of stenosis. Diversion of the urine is an indispensable preliminary. Even more indispensable, he says, is the retention in the vein graft of its blood content. The segment of vein is tied at each end and the blood thus imprisoned serves to nourish the graft until it "takes." This gives it strength to resist the retraction of the skin in the tunnel made for it. He has traced the process in experiments on dogs.

*Ambulant Treatment of Fractured Humerus. H. Iselin.—p. 248.
Epidemic Encephalitis at Zurich. H. W. Maier.—p. 249. Cont'n.

The Ovaries and Functional Hemorrhage from the Uterus.—Meyer-Ruegg presents the various theories in vogue on this subject, his own conviction being that functional uterine hemorrhage is not due primarily to the ovaries. "The nervous system or constitutional causes may be primarily involved, or the structure of the uterus. But removing the ovaries or devitalizing them with the roentgen rays breaks up the chain of processes which eventuate in menstruation, and this breaking of the chain occurs at a point where all the wires cross, that is, in the follicular apparatus. We are thus able to arrest menstruation entirely, but it is beyond our power to regulate it."

Fracture of the Humerus.—Iselin comments on the new light thrown on fracture of the humerus below the tuberosity by roentgenography from the axilla. This has shown that the sagittal displacement is usually much greater than would be suspected when examined from other planes. Ordinary extension does not suffice; it requires not only horizontal, sagittal extension but also diagonal adduction in the horizontal plane to correct the fracture. He gives illustrations of the roentgen findings and of the device with which he corrects the displacement while the patient is allowed to be up and about. The arm is held horizontal, the hand on the other shoulder, the entire arm resting on a thick upholstered cotton pad worn around the trunk, extending from the axillae to the waist, with a broad strap passing over the arm and over the hand on the other shoulder. This answered its purpose admirably in a number of cases as he describes.

*The Pathologic Importance of the Proteins in the Urine. J. Lanfranco.—p. 59.

*Frambesia in Peru. Buenaventura Burga.—p. 72.

The Proteins in the Urine.—Lanfranco agrees with those who think there are not so many varieties of protein in the

urine as some allege. On the other hand, he declares, normal urine in the kidney is absolutely free from proteins of any kind. Among the proteinurias for which the liver is responsible, he lists the albuminuria of puberty, cyclic albuminuria, the albuminuria of the newly born, and alimentary albuminuria. There is also the proteinuria of endocrine or of cardiac origin and of chronic infections. In the latter the multiplicity of the lesions deprives the albuminuria of any exact diagnostic or prognostic value in respect to the kidneys.

Frambesia in Peru.—Yaws or frambesia is called *cuchiye* in Peru; it is usually mild and disappears without leaving a trace, but recurrence has been known. Two cases are described, and the discovery of *Treponema pertenue* in the lesions suggests that the disease might appropriately be called Castellani's treponemosis.

Obliteration of Hemorrhoids.—Boas' method of obliterating hemorrhoids by injection of alcohol into the nodules was described in THE JOURNAL, Feb. 14, 1920, page 497. He here gives minute directions for the procedure and emphasizes the fine results he has obtained in his fifty cases to date. The vacuum glass he uses to draw the hemorrhoids out from the anus fits over the entire anus region, and he applies the vacuum suction sometimes for as long as thirty minutes, to be sure that all the nodules have been sucked out. Even when the hemorrhoids protrude so that suction is not necessary, he usually applies it to make sure that no nodules will escape treatment. If there is much tendency to bleed, he gives three or four rectal injections of a 5 per cent. solution of calcium chlorid the day before.

When returned to the bowel after injection of the alcohol, the nodules shrivel and heal by a kind of thrombophlebitis process in three or four weeks and the mucosa finally feels quite normal. The whole process in the rectum is scarcely noticed by the patient, and requires no after-care as is necessary when the injected piles heal outside the anus. He rubs the extra-anal mucosa with petrolatum and is careful not to allow this mucosa to be pushed inside, as it may become irritated by escaping alcohol and possibly ulcerate. If any nodule protrudes anew after defecation it may be necessary to inject it anew with alcohol or allow it to heal outside the anus. In four of his fifty cases this treatment was applied on account of recurrence after excision some years before. The healing was complete in more than 50 per cent. of his cases in one or two weeks, including 25 per cent. healed in from four to eight days. With this technic the sphincter is left intact, and the results were as satisfactory in the severest as in the mildest cases, while the certainty and the permanence of the cure surpass, he reiterates, even what can be realized with the knife.

Duodenal Tube Reveals Occult Bleeding.—Seidl uses a soft duodenal tube to obtain contents from the cardiac and pylorus regions of the stomach and from the duodenum, to detect occult hemorrhage and locate approximately the source of the bleeding. In some cases of certain ulcer in stomach or duodenum the tube findings were positive when no trace of blood could be found in the stools on three examinations, at intervals, or else bleeding hemorrhoids rendered the findings unreliable. He gives the details of twenty-six of his total seventy cases thus examined, showing the instructive findings as the patient lies on his left side,

with the tube introduced for 50 cm. or on the right side, tube 50 cm., or the tube is carried down into the duodenum. The findings were constantly negative in patients showing no symptoms of an ulcer. The stomach and duodenal contents thus obtained can be used for other analysis, and repeated tests of this kind will distinguish ulcer from cancer, show the progress under treatment and the indications for operative measures. After gastro-enterostomy for ulcer, the ulcer did not heal unless a systematic dietetic treatment of the ulcer was enforced thereafter. The soft duodenal sound does not cause erosions which might obscure the findings.

Harmless Diabetes.—Wynhausen and Elzas prefer this term to "renal diabetes," the term usually employed to express glycosuria with normal sugar content of the blood and very slight if any of the usual symptoms of diabetes. This diabetes innocens, as they call it, is not rare as they have records of over thirty cases in a comparatively brief period, and they analyze most of them here. The disturbances are so slight that no one seeks medical aid for them, and the discovery of the glycosuria is usually accidental. It can be classed as belonging to this harmless group when the sugar content of the blood keeps normal before and after the test breakfast or does not go above 1.5 or 1.7 per thousand. They recognize four groups, all with normal blood sugar content, but classified according to the amount of glycosuria after the alimentary test. The harmless character persists in three of the groups, but in the fourth, in which there is slight glycosuria fasting but it runs up high after the alimentary test, symptoms suggesting true diabetes develop in time. The experiences related suggest further that it is possible for the sugar content of the blood to be above normal, and yet the glycosuria persists in this harmless type, showing no tendency to progress.

Tenderness on Percussion in Diagnosis of Gastro-Intestinal Disease.—Uhlmann insists that the sensitiveness to tapping is far more instructive than mere tenderness in the differentiation of inflammatory from nervous-functional processes, for localization of a pathologic focus and control of its progress or subsidence, for discovery of a localized painful point, and for estimation of irritation of the peritoneum. He gives examples of each of these and describes the zone of extra tenderness that usually encircles the point most sensitive to the percussion hammer. The sensitive zone is so clearly outlined by the patient on repeated examination that the method is actually objective.

Effect on Gastric Secretion of Extracts of Endocrine Glands.—Boenheim devotes nearly fifty pages to the account of his tentative treatment in this line, in 154 separate experiences. The findings are tabulated for comparison. A marked regulating influence on gastric hyperacidity was evident from thyroid and pituitary treatment, and on subacidity and anacidity from pancreas extract. Thymus and thyroid extract have a similar but less pronounced action. With normal acidity, he found that thymus and pituitary increased while thyroid and ovarian treatment reduced the acidity; after a test breakfast digestion of albumin was checked. He says that these endocrine extracts, injected subcutaneously, seem to have a potent action on gastric secretion, transforming it, probably by their effect on the nervous mechanism of the stomach. Some of his conclusions conflict with generally accepted views, but the results obtained justify, he says, continuing research in this line both experimentally and in the clinic, as the secretory functioning of the stomach can thus be modified at will by organ extracts, and the effect lasts long after the treatment has been suspended. His series of climacteric neuroses confirms that excessive ovarian functioning checks gastric secretion, while insufficient ovarian functioning entails a tendency to hyperacidity.

*Atypical Chronic Anemia. F. Herzog.—p. 285.
*Atypical Hemolytic Jaundice. K. Beckmann.—p. 301.
*Polycythemia. G. Herrnhaiser.—p. 315.
*Origin of Albuminuria. Recka Mandelbaum.—p. 331.
*Acute Yellow Atrophy of the Liver. W. Weigelt.—p. 342.
*Influence of Muscular Work on Sugar Content of the Blood. O. Brösamen and H. Sterkel.—p. 358.

Atypical Chronic Anemia.—Herzog describes two cases of chronic anemia, in men of 23 and 34, for which no cause could be discovered during life or at necropsy. The younger man died suddenly, during an apparent remission, from pulmonary edema. The blood picture was that of secondary anemia; there was no gastric achylia while the iron reaction in the organs excluded Biermer's pernicious anemia. The other man's anemia was of seven years' standing with various remissions, and intestinal hemorrhages for a time but the anemia had preceded them. There was no very active regeneration of blood, but the abnormality was too slight and of too long duration to be classed as aplastic anemia. The findings in the tongue resembled those of true pernicious anemia, but the lack of gastric achylia and the recent benefit from blood transfusion seemed to exclude this. The patient is still under observation.

Atypical Hemolytic Jaundice.—Beckmann reports the minute details of two cases of supposed hemolytic jaundice in which there were no signs of extra susceptibility of the blood corpuscles to hemolysis. But it proved possible by applying provocative measures to the spleen—as in malaria—to render the erythrocytes abnormally susceptible. In two other cases in which the erythrocytes were found already exceptionally fragile, these provocative measures failed to induce any appreciable modification. In one case of hemolytic jaundice, clinically normal conditions were restored after splenectomy except for slight anisocytosis and slightly abnormal susceptibility of the erythrocytes. He adds that no traces of any special hemolytic substances could be discovered. The provocative measures aimed to reduce the resisting powers of the organism in general, or of the spleen alone, and thus exaggerate the destruction of the blood. The spleen was lightly massaged and then douched with alternately hot and cold water, and the region was then exposed daily to the mercury quartz lamp from front and rear for periods increasing from five to sixty minutes in the course of the week, the provocative measures concluding with a single roentgen exposure of three quarters of the full dose. The patients were men of 37 and 34, and the child of the younger man showed a similar tendency to anemia and slight jaundice with enlargement of the spleen. The provocative measures induced prolonged extra susceptibility of the erythrocytes; it was evident six months afterward in the man reexamined. The stools were normally colored in both and there was urobilinuria, and the extra susceptibility of the erythrocytes coincided with increased numbers of erythrocytes but mainly of the microcyte type. Microcytosis seems to be typical of hemolytic jaundice, and suggests some causal connection. Removal of the spleen may cure the tendency completely and is usually followed by marked benefit, even in the familial form although it may not be lasting here. In one such case the spleen weighed $2\frac{1}{2}$ pounds and the erythrocyte susceptibility index dropped from 0.66 to 0.52, very close to the normal range.

Polycythemia.—Herrnheiser argues that not only increased production of erythrocytes but reduction in their normal destruction are involved in the production of true polycythemia rubra, and there may be various causes for this. In a case described with the metabolic findings nothing to indicate primary irritation of the bone marrow could be discovered. In such cases, he adds, special attention should be paid to detection of constitutional anomalies, to the cholesterol metabolism and to the behavior of the frequent orthostatic albuminuria. The patient in his case was a robust agricultural worker of 18 who complained of agonizing headaches, fatigue and dizziness. He ascribed the symptoms to a sunstroke the summer before. The spleen was not enlarged and the blood pressure was within normal range, but there was pronounced orthostatic albuminuria, and the cholesterol content of the serum was below normal. No relief was obtained from a single lumbar puncture. Venesection seemed to benefit more than raying the long bones, but as spontaneous remissions are sometimes observed, Herrnheiser does not regard this as conclusive.

Origin of Albuminuria.—Mandelbaum comments on the general assumption that while the diseased kidney may not

permit urea, salt or even water to pass, yet it will let the big albumin molecule filter through without interference. Clinical examination of sixty-two patients with various forms of kidney and bladder disease and a series of experiments on rabbits have demonstrated that this view is incorrect. The inflamed kidney epithelium does not allow the passage of serum albumin. Hence it follows that the albumin found in the urine does not come from the blood but must be secreted by the renal epithelium itself, an active, vital function or a reaction of the epithelium cells. Conditions here are the same as with meningitis; normally there are only traces of albumin in the cerebrospinal fluid, but when the meninges are inflamed then the albumin content rises. All the tests showed that filtering ascites fluid, pleural effusions, blood serum and similar fluids through a delicate animal membrane, such as the rabbit and cat intestine, the albumin content of the filtrate was about the same as that of the original fluid, and the proportion of albumin to globulin persisted unmodified, but when the membrane was hardened or otherwise rendered less permeable, the globulin was arrested first; with increasing impermeability none of the albumin passed into the filtrate or dialysate. Applying these findings to conditions in the kidney, either the proportion of globulin and albumin should be the same in the urine as in the blood, or the albumin should predominate. But this is not the case with diseased kidneys. A relative preponderance of globulin has been found in the urine in simply congested kidneys and in orthostatic albuminuria. This conflicts most decidedly with the assumption that the albumin merely filters through from the blood.

Acute Yellow Atrophy of the Liver.—Weigeldt reports the discovery of vacuolar inclusions in about 50 per cent. of the neutrophil polymorphonuclear leukocytes in a case of acute yellow atrophy of the liver in a man of 27. The number of erythrocytes and the hemoglobin percentage are usually above normal in this disease, and the neutrophils are above the usual figures, with displacement of the blood picture to the left. But these findings have no differential significance as they are common to phosphorus poisoning, infectious and other forms of jaundice. If these vacuolar cell inclusions are confirmed by others, this will aid materially in the diagnosis. The article is illustrated. Weigeldt has not been able to find any record of such intracellular findings in the accessible literature.

Influence of Muscular Exertion on Sugar Content of the Blood.—Brösamlen and Sterkel found a marked reduction in the sugar content of the blood in ten healthy persons after physical exertion leading to rapid fatigue. The maximum reduction was reached in from one and a half to four hours after the exertion. Corresponding tests in four diabetics were followed by a pronounced rise in the sugar content, beginning at once after the exertion and keeping up for several hours. The curve is not regular but shows slight rises and falls. The findings on the whole confirm that diabetes is essentially a pathologic excessive glycogenolysis. There did not seem to be any connection between the intensity of the reaction and the severity of the diabetes, in his cases, and in two of the tests a slight reduction of the blood sugar content was found. The findings are apt to be misleading unless series of tests are made, and it does not seem to be possible to modify the exertion-sugar curve by dieting or changing the mode of life.

Partial Immunity, with Depression of Virulence.—Morgenroth, Biberstein and Schnitzer have been experimenting with superinfection, or superposed infection, as this field of investigation has thus far resisted any attempts to harmonize its findings with the prevailing theories in regard to immunity, and as experimental studies in this field seemed to promise good results. They started with the commonly accepted theory that the infected organism acquires an immunity against superinfection, and against a like, superposed infection, but they became interested in the investigations of Landsteiner and Finger, who maintain that the organism infected with syphilis is by no means immune to a new syphilitic infection, as has been commonly supposed. Their experiments demonstrated that mice with an experimental, chronic streptococcus infection, streptococci being found in the blood and in the organs, possess immunity toward a superinfection with streptococci, as is shown by the fact that when given a streptococcus dose, such as will kill normal animals within twenty-four hours, they show no change in their behavior. They are immune not only toward the strain of streptococcus with which they were primarily infected but also against foreign strains of streptococcus. However, this immunity is not absolute but relative, for it is broken down by a strain of especially high virulence, in which case the infection runs an acutely fatal course, as in the controls. This partial immunity does not lie in the fact that the superinfection does not "take"; on the contrary, the streptococci used for the superinfection appear in the blood and organs, and by the aid of especially "marked" strains could be shown to remain present for some time. The partial immunity consists, therefore, merely in a depression of the virulence of the infection. This immunity was developed in from six to twenty-four hours after the experimental infection. It does not seem to have anything to do with anaphylaxis, but presents a new kind of immunity. They theorize that the passing of an acute infection into a chronic phase is conditioned by the development of this "depression immunity." The latter is not the result of the chronic infection, but every infection that is not rapidly fatal has its course determined by the depression immunity. Each phase of the infection is the result of the antagonism between the causal germ and the degree of depression immunity at the moment. This assumption throws light on natural immunity and all other forms of immunity which do not fit into the picture of immunity from antibody production. They suggest in conclusion that certain hormones which normally regulate the growth of the cells may be the factors in this depression immunity.

Vascular Changes in Syphilis and Nicotin Poisoning.—Beneke reports three cases of nicotin poisoning that presented peculiar vessel symptoms: vascular dilatation, degeneration of the media, marked fatty degeneration of the intima, with relatively slight sclerosis; the coronary arteries and other branches of the aorta were especially implicated. Beneke regards it as significant that a predominating nicotin poisoning could cause such severe arterial changes. He thinks in view of these findings, and the fact that smoking is so widespread, the assumption that nicotin poisoning may be the primary cause of many cases of grave arterial changes, or at least a strong contributory factor, appears to be well founded. The three men were 42, 44 and 48 years old, and had been addicted to smoking many strong cigars or cigarettes. No abuse of alcohol was known and there was nothing to suggest syphilis or other infection. Two had succumbed to coronary failure.

Thermopenetration in Treatment of Chilblains.—Grünbaum has tried the mercury vapor lamp repeatedly in the treatment of chilblains, as it has been so warmly recommended of late, but he has not found it essentially superior to other methods. For the past year he has therefore been trying another method and is enthusiastic over the results. In treating for other diseases, he discovered accidentally that chilblains improved rapidly following thermopenetration and soon disappeared entirely. He therefore began to use thermopenetration as the routine treatment for chilblains and he is convinced that it is far superior to all the other usual forms of treatment. He is inclined to think it will prove efficacious in severe frostbite, but has not had an opportunity to try it out yet.

*Postoperative Tetany and Parathyroid Grafts. E. Borchers.—p. 293.
*Extraperitoneal Abdominal Incision for Nephrectomy. K. Hofmann.—p. 297.

Carcinoma Dosage in Radiotherapy.—Lehmann assumes that nowadays almost every surgeon gives his patients with carcinoma of the breast prophylactic raying, following an operation. He states that he and his associates in the surgical clinic at Rostock have been using this method for the last seven years with the result that the freedom from recurrences for a period of three years has decidedly increased, being formerly 33 and now 47.5 per cent. of the cases coming to operation. He finds that in cachectic patients carcinomas are not at all sensitive to roentgen rays, whereas in the aged, carcinomas are often of slow growth and in that case easier to check with roentgen rays. Chancroid of the lip requires much more than 100 per cent. of the erythema dose, and radium therapy will usually prove more efficacious than roentgenotherapy. While no doubt progress is being made in the technic of roentgenotherapy as applied to carcinoma of the breast, Lehmann does not think it is wise to be over-jubilant for fear of bringing the method into discredit.

Postoperative Tetany and Transplantation of Parathyroid Glands.—Borchers adds two more cases to the list of those in which parathyroid grafts have been successful in the treatment of postoperative tetany. It is unfortunate that ten years ago many surgeons, on the basis of animal experimentation, reached the conclusion that the transplantation of parathyroid glands from one person to another in treatment of tetany was useless. Their skeptical attitude was not justified, for even at that time excellent clinical results had been secured which Borchers is inclined to regard as more important than theoretical premises deduced from animal experimentation. Many authors had shown by animal experiments that the transplanted glands would not preserve their structure and function, but in man the glands, as can now be shown by a whole series of cases extending over several years, do preserve their structure and function, or at least a structure and function that protects. From this the important conclusion may be derived that animals behave functionally different from humans. That there are some failures still is only to be expected, but to date parathyroid grafting is the only treatment of chronic postoperative tetany that offers any chance for success.

The Extraperitoneal Abdominal Incision in Nephrectomy.—Hofmann denies that there is no essential difference between the extraperitoneal abdominal incision as recommended by him and paraperitoneal nephrectomy. He defends his method of an anterior longitudinal incision along the border of the rectus abdominis, or between the recti abdominis or even directly in the linea alba, analogous to Saenger's transperitoneal procedure, for the reason that thus the hilum of the kidney is brought into the center of the field of operation. The method is adapted to nephrectomy for any cause.

Exact Localization of the Center of the Cancer in Roentgen Treatment.—Borell states that most roentgenologists (himself included) are not in possession of all the special instruments for determining the exact distance and localization of the focus from the surface of the body which it is so necessary to know in order to decide what dosage to use and in order to adjust the tube so that the central rays will fall on the center of the focus of infection. These exceedingly important points do not seem to be given by all the careful attention that they deserve. He describes a method that is available to all and which he has found very helpful in the absence of the more delicate measuring instruments, such as the iontquantimeter, etc. It is adapted from the principle of roentgenologic localization of foreign bodies at any depth. A roentgenogram is made of the patient in a position which is exactly noted by a definite system that is described in detail, and then the tube is moved 6.5 cm. horizontally to one side, and another exposure is made on the same plate. This double exposure furnishes the basis for the localization of the foreign body, or in the present instance, of the center of the cancer, by two homologous points in the foreign body shadows. By means of Fürstenau's bathometer, which is provided with three different scales, the vertical distance of the foreign body, or of the site of the infection, is then quickly determined. Borell has been using the method for several months, and states that he has noted unusually good results in the regression of carcinomas by reason of the more exact technic that this method made possible.

*Radiotherapy for Mammary Cancer. W. H. Jolles.—p. 567.

Anomalies in Head and Neck of Femur.—Zaaier refers to the dystrophy of the head or neck of the femur in the young such as has been described by Legg, Calvé and Perthes. It occurs usually between 5 and 10, with an extreme range of 3½ to 12. Before the publications of the above writers (1910) such cases would have been labeled tuberculous coxitis and treated accordingly. This mistake is still made, Zaaier says, by those not familiar with the literature of the last ten years on this osteodystrophy of the hip joint. If there is pain, the joint must be relieved from weight-bearing, with correction of excessive adduction if required, but otherwise the child can be left unmolested. The final outcome may be perfect functioning or a condition like that with severe deforming arthritis. Usually, however, the final condition is between these extremes, with very little disturbances. The head may

assume a valgus position, with the neck in a varus position. It is important to keep the child under supervision and correct in time any tendency to excessive varus deformity.

In 1914 a compilation of fifty-five such cases was published, all but eleven in boys, and in 66 per cent. of the cases there was a history of trauma of the hip joint, and this was probable in all. The injury at the junction of the epiphysis had evidently interfered with the nutrition of the head and neck. Zaaier reports further the case of a girl of 12 who had tripped and fallen, and the neck and head had become entirely detached from the shaft of the left femur, complete epiphysiolysis. The dislocation was corrected and the parts healed in place in a plaster cast. About a year and a half later, a similar epiphysiolysis occurred on the other side. This healed likewise in a cast and, except for slight stiffness, the gait is now normal. Köhler has also published a case of bilateral femur-epiphysiolysis; it occurred while jumping rope. With the Osgood-Schlatter disease of the tuberosity of the tibia, these three form a group in which there may be occasionally pain but there is no inflammation, and the clinical manifestations are insignificant in comparison to the often gross anatomic lesions. The Osgood-Schlatter epiphysitis of the tibia occurs at 14 or 15, and juvenile epiphysiolysis from 14 to 18. He explains how the growth at these ages predisposes to these anomalies. The question of complete bed rest should be considered; it might ward off further deformity if applied during the first phase of the Perthes' disease, and it is certainly beneficial in the Osgood-Schlatter epiphysitis of the tibia. But it is a difficult matter to enforce, for children who feel perfectly well and have no pain. With actual fracture and dislocation at the epiphyseal line, more or less strict bed rest for several months has to be enforced in some cases.

*Acetone in Spinal Fluid from Standpoint of Functions of the Choroid Plexus. J. Koopman.—p. 1346.

Present Status of Vitamin Question. B. M. van Driel.—p. 1350.

Quantitative Technic for Precipitation Test for Syphilis.—Bok explains that the Sachs-Georgi reaction is like the first phase of the Wassermann reaction only much more intense. This precipitation of colloids is merely a chemical process, and can thus be studied and afford a deeper insight into the nature of syphilis than the tests which superpose two biologic processes. He describes a modification of the technic which allows quantitative classification of the findings, saying that the original qualitative technic is absolutely unreliable. The nonspecific reactions which occur only with 0.1 or 0.2 can be disregarded; with syphilis the index is higher than this. The test is more sensitive than the Wassermann and is simpler and takes less time. A normal beef heart provides a sensitive reagent for the test, and the cerebrospinal fluid is used undiluted in a set of five test tubes.

Acetone in the Spinal Fluid.—Koopman reports that 10 or 15 c.c. of acetone injected subcutaneously or by the vein did not pass into the cerebrospinal fluid, while inhaled chloroform was constantly found in it. His tests were made on six rabbits. In a fatal case of hemorrhage in the suprarenal, he found 12 mg. of acetone per liter in the spinal fluid, and occasionally in epileptics, he detected acetone in the spinal fluid. The intrameningeal pressure of the fluid was always abnormally high in the cases of diabetic coma he has examined. With severe acidosis, but no coma, he has never found the spinal fluid normal when the pressure was high, but in three cases he witnessed the prompt rise in the pressure when the fluid contained acetone and sometimes diacetic acid, and the pressure was normal when first examined. This suggests that the acetone irritates the choroid plexus and whips it up to secrete more of the cerebrospinal fluid. The same

may occur with urea, chlorids and albumin, and this has suggested the question whether the choroid plexus functioning may not be compared to that of the kidney, and whether it may not function vicariously for the kidneys to a certain extent in some conditions. He adds that this theoretical assumption justifies tests of the permeability of the choroid plexus along the lines of the functional kidney tests, and also anatomic study of the choroid plexus in cases of death from uremia or diabetic coma.

*Is the Lasègue Symptom from the Nerves or the Muscles? J. Helweg.—p. 113. Begun in No. 7, p. 97.

The Lasègue Sign in Sciatica.—Helweg presents an array of arguments to prove that the pain with the Lasègue sign is from the muscles, not from the nerves. He insists that the sciatic nerve is not responsible for the pain experienced when the extended leg is lifted passively from the plane of the bed, the knee still extended, and declares that he does not know of a single instance on record of lesions having been found in the sciatic nerve of persons who had suffered from sciatica during life. He also recalls that the sciatic nerve is accessible to direct pressure only in the popliteal space, where the popliteal nerves can be palpated. In his examination of 300 patients with sciatica, he never found the popliteal nerves more sensitive to pressure on the side of the sciatica than on the sound side. Tenderness along the course of the sciatic nerve may be due to the superposed muscles, but there is no evidence to date that it is due to the sciatic nerve itself.

*General Arc Light Treatment of Laryngeal Tuberculosis. N. R. Blegvad.—p. 129. Begun in No. 6, p. 81.

Phototherapy of Laryngeal Tuberculosis.—Blegvad here describes his success in 52 cases of laryngeal tuberculosis in which treatment was with general exposures to the carbon arc light. Each case is reported in detail, with illustration of the findings before and after in a number. The patient reclines, undressed, under the light from four powerful (20 amperes) arc lights, four patients at a time sharing the light bath. From fifteen minutes at first, the exposures are lengthened in a week to an hour and were never given longer than this. Among the 74 patients thus treated, the laryngeal tuberculosis healed completely in 17. In 16 the tuberculous process continued its course unaffected. Most of the patients had concomitant pulmonary tuberculosis, and in an advanced stage in some. The ulcerative processes in the larynx promptly subsided under the phototherapy, sometimes supplemented with local measures, especially the galvanocautery applied deep in the lesion, according to Grünwald's method. The course of treatment lasted from two to four, six or more months; some of the patients took two courses with several months' interval.

*Methyl Alcohol Poisoning and Blindness. J. F. Harboe.—p. 379.

Volvulus of Sigmoid Flexure.—Summarized May 1, 1920, p. 1287, when published elsewhere.

Retrograde Incarceration of Inguinal Hernia.—Mamen compares a case which he reports in detail with the 62 cases of Pólya's international compilation; the ages ranged from 7 to 76. The 2 cases in which no operation was attempted

terminated fatally the third and fourth days. The intestine in the hernia forms a W, the center loop usually projecting back into the abdominal cavity. The intestine was considered reducible in 31 of the cases, but 4 in this group died. In 3 of the cases there were three loops of intestine involved. The hernia in these cases is usually very large and of long standing. In some of the cases the abdominal wall protruded above the hernia, and a palpable tender tumor was evident in some, as in Mamen's own case. If more than one loop is found in a hernia, further investigation is imperative.

Treatment of Joint Lesions.—Usland has been converted to Willems' method of early active exercise of the suppurating joint by his success in the case of a boy of 10 with a purulent process in the knee which had been cut by a fall on a broken bottle. The immobilizing bandage and the catgut sutures were removed on account of the streptococcus infectious process, nine days after the accident, and active movements of the knee were made every hour. The temperature dropped at once with the active movements. The boy was able to flex his knee to 90 degrees without pain by the second day, and to 180 degrees the sixth day, and was up and about in less than two months. By the end of the two months the skin had healed completely and the knee was so flexible that the boy could touch his nates with his heel. The ideal drainage of the joint under the influence of the active movements seems to be the main element in the favorable outcome, as also the remarkable absence of pain in comparison to the pain in an immobilized joint.

Vagitus Uterinus.—Gjersøe reports that during forcible delivery of a primipara, when the hand was introduced into the uterus a cry was heard from the interior of the uterus, clearly audible to the nurse and the two assistants, and it was repeated several times in the course of ten minutes. Extraction finally succeeded, with forceps, and mother and child are doing well. Fully twenty minutes elapsed between the first vagitus uterinus and the extraction, but the child was not especially asphyxiated and no attempt at resuscitation was required, the child screaming at once. The entering hand had evidently introduced air into the uterus. The cry testifies that a child can be born with air in its lungs, but this can scarcely occur without artificial measures to aid delivery.

Diabetes and Influenza.—Motzfeldt remarks that Joslin in his compilation of 1,000 cases of diabetes was not able to trace it to an infectious disease in more than 36 cases. During the influenza epidemic of the nineties, several reported instances of diabetes following influenza, but in the recent epidemic he knows of only 2 published cases of the kind, and in these it was merely the exacerbation of latent diabetes. He here relates 4 cases in which the first symptoms developed directly after an attack of influenza, and in one of the cases, there was pain in the tender pancreas. The patients were 14, 15, 20 and 35 years of age, and the diabetes was mild; reexamination from ten to eighteen months later showed tolerance for 150, 300 or 500 gm. bread, and in some, alimentary glycosuria.

Methyl Alcohol Intoxication and Blindness.—Harboe reports a case in which the man was under observation for a week before the cause of the disturbances was discovered, the man denying drinking liquor. The bottle from which he had imbibed was finally found and still contained some of the "spirit" which proved to be pure methyl alcohol. He could count fingers at half a meter with the right eye and with the left detect screening of the light at the same distance. The visual field was much restricted. Nine charts of the fields are reproduced showing the gradual improvement, but by the end of four months there was still some paresis of accommodation. There were no signs of the usual retrobulbar neuritis at first, but some atrophy of the optic nerve finally became evident. Treatment is usually with lavage of the stomach and enemas with measures to induce diaphoresis. In conclusion, Harboe cites the literature on poisoning by wood alcohol, and mentions Kafka's report in 1919 of eleven cases of retrobulbar neuritis in which exclusion of all other causes seemed to point to this.

OFFICIAL METHODS OF CONTROL OF REMEDIAL AGENTS FOR HUMAN USE*

G. W. McCOY, M.D.

Director, Hygienic Laboratory

WASHINGTON, D. C.

Control of remedial agents by the government rests on the interstate commerce clause of the constitution, under which the Food and Drugs Act is enforced by the Bureau of Chemistry of the Department of Agriculture, and the law governing the sale of serums, viruses, toxins and analogous products which is enforced by the Public Health Service of the Treasury Department. Control is also exercised over all drugs, serums, etc., that are imported.

This preliminary statement is made to clarify the situation with respect to some notorious frauds, which well-meaning persons have rightly felt ought to be suppressed but which on further investigation were found not to be the subject of interstate traffic. The suppression of these logically rests with local authorities, state or municipal.

THE FOOD AND DRUGS ACT

With respect to domestic preparations, the Food and Drugs Act, in its bearing on remedial agents, is chiefly a measure designed to secure truthful names and statements. This control is necessarily divided into that which is intended to apply to preparations designed primarily for the use of the laity direct, and that which is applicable to medicines ordinarily prescribed by physicians. I need not tell this section that there is much overlapping of these groups.

This law is designed to secure truthful names and truthful statements; but if one stops to consider what that means, one will see that in doing this the federal Food and Drugs Act insures to the purchaser, physician or layman, an honest product. It means that when the druggist orders from the wholesale dealer a fluidextract, this law tends to insure that he will get the United States Pharmacopeia preparation. If a bottle of tablets is labeled "Aspirin, 5 grains," this law provides punishment for the shipper of the package in interstate commerce if the tablets do not contain 5 grains of acetylsalicylic acid. As an example, last year many shipments of alleged castor oil capsules, although labeled to be castor oil, contained from 50 to 70 per cent. of cottonseed oil, and were made the

subject of official action. The federal Food and Drugs Act protects and makes respected the confidence that the patient naturally gives to his physician and to his druggist.

In connection with the enforcement of this law, the courts generally take a broad view of the intent of the act, and in spite of the delays incident to any legal procedure, eventually it is usually possible to secure conviction. Even if the actual wording of an advertisement is cleverly presented and possibly literally truthful, if the impression conveyed to the purchaser is not one that is justified by the composition of the preparation, the law may be invoked.

In the case of "patent medicines," the law requires that the label or package shall not contain any statements of therapeutic or curative effect that are false and fraudulent. The use of the words "cure" or "remedy" is not forbidden; but they must be used only for medicines that actually are cures or remedies for the conditions named on the label. The placing on the label of the names of diseases is taken to imply that the medicine contained in the package is in itself a treatment for the diseases or conditions named.

The requirements with respect to labeling have resulted in the use of the words "cure" and "remedy" becoming comparatively rare, and such expressions as "will often relieve" "will frequently tend to overcome," "will aid nature to restore," "may sometimes be used with benefit," "some cases will yield to the treatment," and similar expressions, are becoming popular. Obviously, a purchaser who wishes to use a proprietary medicine, and uses it in the face of no stronger assertions than these, is within his rights in following the dictates of his own judgment. In this connection, it is remarkable how vague and noncommittal advertisements may be in medical journals and yet succeed in impressing medical men. Not long ago there appeared a rather widely circulated advertisement of a biologic product, which, when carefully read, made no definite statement or claim beyond the one that the preparation "is indicated" in certain diseases, yet physicians interested in truthful advertising were generally inclined to consider that the advertisement was unwarranted and unreasonably optimistic. When we consider how loosely the word "indicated" is used in connection with medicinal preparations, we are scarcely in position to take exception to such statements as this.

An officer of the Public Health Service, detailed to the Bureau of Chemistry at the request of the Secretary of Agriculture, and assisted by two other officers from the Public Health Service, has charge of the administration of the drug side of the Food and Drugs Act, except for the matter of raw or crude drugs.

* Chairman's address, read before the Section on Pharmacology and Therapeutics at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

MISLEADING STATEMENTS IN TEXTBOOKS

It may come as something of a surprise to the members of the section to learn that perhaps the most effective bar to the control of proprietary medicines is the existence in textbooks of therapeutics and of medicine of loose and even misleading statements as to the value of remedies. It is when the manufacturer seeks to justify the placing of names of diseases on his label that we are confronted with misleading quotations from textbooks.

The searching of medical literature for quotations to support claims of proprietary remedies has become something of a specialty, and attorneys tell me that it is possible to secure quotations from highly respectable authorities referring to almost any drug that is put into a proprietary remedy. I recently appeared as a witness opposing the claims of a proprietary remedy in which oil of eucalyptus was the agent asserted to be of value in the treatment of tuberculosis of the lungs and other pulmonary diseases, and, quite in accordance with expectations, the attorneys for the manufacturers of the preparation were able to quote statements from a number of reputable textbooks on therapeutics and materia medica which went a long way toward justifying the contention that the advertising was based on substantial medical evidence.

CONTROL OVER DRUGS AND BIOLOGIC PREPARATIONS

With respect to agents called drugs in the ordinary sense and designed primarily for use by physicians, the rulings under the Food and Drugs Act have been that the government should not interfere with the privilege of a physician to use any agent he sees fit to employ, differing in this respect from the control exercised over biologic products.

With respect to the control over "serums, viruses, toxins and analogous products," to quote the wording of the law of July 1, 1902, the situation is somewhat different. The wording of the law clearly indicates that it was the intention of Congress to restrict the use of preparations coming under this law to such as had therapeutic or prophylactic activity; in other words, it was intended to prevent the practice of deception, even on the physician, as well as to guarantee safety. At first sight it might seem that the administrative officer's functions were reasonably clear and simple; but really we find that the determination of therapeutic or prophylactic value is a matter of much difficulty frequently—at times, indeed, it is impossible.

Perhaps an example or two will clarify this. A few years ago there was a rather general acceptance among bacteriologists of a small anaerobic gram-positive organism as the cause of typhus fever, and soon after the apparent demonstration of the etiologic relation of this organism to typhus an application was filed for a license for antityphus vaccine made from the organism in question. No evidence was presented to prove the worth of the vaccine, but it was insisted by its proponents that it must be of value, being made from what was conceived to be the cause of typhus fever. It was felt that the importance of the subject demanded an attempt to ascertain the facts in an experimental way, before authorizing the use of the vaccine. Without going into the details of experiments that took many months to complete, it was conclusively shown that the vaccine was quite without the slightest effect in the prevention of experimental typhus under rigidly controlled conditions, and on this evidence a license was denied.

Another class of biologic preparations, for which licenses are constantly being sought, are alleged remedies for tuberculosis; here again the attitude has been that evidence of usefulness satisfactory to an impartial investigator must be secured before a license will be recommended. Thus far, in each case in which tests have been made, it has been found that the alleged tuberculosis remedy has been without value, and licenses were therefore refused.

When it is possible to secure experimental evidence within a reasonable time, this is insisted on. The most difficult cases, however, are those in which it is impossible to secure evidence from laboratory experiments. Let us take, for example, the respiratory infections, particularly the rather ill-defined group including "grip," "colds" and "influenza." It is not possible to submit the bacterial vaccines that are claimed to be of therapeutic or prophylactic value to the crucial tests of controlled laboratory experiments. To secure the data by controlled clinical experiments, save in most exceptional cases, is impossible. What shall the administrative officer do? He may feel that these vaccines are worthless, but he cannot prove it, and, on the contrary, he is confronted by a mass of uncontrolled clinical data which indicate the usefulness of the agent. As a result, in order to avoid the possibility of doing harm by depriving people of an agent which it is barely possible may be of value, he recommends the granting of a license, though he may be reasonably certain that the preparation is not of value, though probably harmless.

It is inevitable that the marks on a package indicating that a preparation is made under government license will be construed by some as a guarantee of efficiency. To obviate this as far as possible, it is required that a statement to the effect that there is "No U. S. Standard of Potency" shall appear on packages of products that are without potency standards. I am glad to say that potency standards are provided for nearly all really useful products, the conspicuous exception being smallpox vaccine.

It is a pleasure to record here the cooperation and the ready acquiescence to administrative decisions on the part of the great majority of manufacturers of serums and similar products. They have withdrawn preparations which we have considered, but could not prove, to be worthless, and have refrained from pressing applications for license for preparations that fell into the same class.

There are certain biologic preparations for which tests and standards are not sufficiently accurate to enable different workers always to get approximately identical results. The best example of this is anti-pneumococcic serum. In the cases of this, of anti-meningococcic serum and of one or two other preparations, the manufacturer is required to make tests that are prescribed, and, if the preparation proves satisfactory, to send samples of the serum together with a copy of the record of his tests to the Hygienic Laboratory, where the tests are repeated and the preparations are finally passed for sale, or rejected, on the basis of the official tests.

The same method, i. e., the testing of each batch of the product, is applied to arsphenamin and neo-arsphenamin, which have been held by the law officers of the government to come under the provisions of the same law that is applicable to serums, viruses, toxins and analogous products.

The testing of preparations in this manner naturally throws a heavy burden of routine work on the controlling laboratory; but every proposal to discontinue this form of safeguarding of preparations is met by objections from so many sources that I suspect we shall have to consider it a fixed part of the routine work of the laboratory charged with the supervision of these products. This has the great disadvantage of taking time and effort from purely research work. Of course, there should be ample resources to carry on the essential routine without curtailing research features; but funds are inadequate to permit this.

The regulations at present require the proper descriptive designations of the product in addition to the trade name. Thus, tubercle vaccine must be marked "Bacterial Vaccine Made from Tubercle Bacillus," and influenza prophylactic must be marked "Bacterial Vaccine Made from the Influenza Bacillus" and such other organisms as may be present in the product.

Within the past year the wide latitude heretofore allowed manufacturers in the dating of preparations with respect to the duration of potency has been replaced by fixed maximum dating requirements.

It is a pleasure to state that the United States is far in advance of older countries in respect to the control of medicinal agents. I well recall the amazement with which a distinguished English physician learned that we would not recommend license, for example, for antipoliomyelitis serum, anti-influenza serum, and various cures for tuberculosis. England is practically without restrictions, and, as the distinguished physician remarked, "American law is the only protection that England has against useless or fraudulent preparations of American origin," the basis of this being the fact that our law applies to materials for export as well as to those for domestic consumption.

There is a very marked difference between the methods employed by the two arms of the government concerned in drug control. Under the Food and Drugs Act, examinations are made of products found in interstate commerce; and if they fail to comply with the required standards or are falsely labeled, appropriate legal action is taken, either by prosecution of the shipper or by the seizure of the shipment. On the other hand, under the law controlling the serums, viruses, vaccines, etc., the aim is to see that no impure or worthless product shall be allowed to enter interstate commerce. This aim is accomplished by a system of licensing manufacturers for various products. No license is granted to any firm until the licensing authority is satisfied that the personnel and equipment of the firm are both qualitatively and quantitatively sufficient to give all reasonable assurance that the products for which license is sought shall be satisfactory in regard to purity and potency.

In addition to the assurance afforded by the licensing system, there is supervision of finished products through the procuring of samples in the open market and the testing of these.

In addition to the activities that have been described, which cover the major fields of federal drug control, we have the prevention of exploitation of obvious frauds through the mails, which is the function of the Post Office Department, and the supervision over liquors and narcotic drugs, which is exercised by the Internal Revenue Bureau of the Treasury Department; but I need not discuss these at this time.

SIGNIFICANCE OF ETIOLOGIC FACTORS IN THE TREATMENT OF PEPTIC ULCER*

FRANK SMITHIES, M.D.

Associate Professor of Medicine, University of Illinois College of Medicine; Gastro-Enterologist, Augustana Hospital; Medical Consultant, U. S. Marine Hospital

CHICAGO

My aim in this report is to stimulate serious scrutiny of methods in vogue in the management of peptic ulcer. That such inquiry is needed is proved by recalling that, although much useful knowledge has accrued to physicians from recent clinical, operative, chemical, experimental and pathologic studies, yet, apart from various surgical procedures, little essential has been contributed to the actual, practical treatment of the affection since the time of Celsus.¹ In various languages, from the period of that clinical patriarch, have similar directions been given for the cure of *ulcus ventriculi*: "Remove or neutralize the acid which causes (sic) the ulcer, and nature will do the remainder."

It would seem to be a painful commentary on the acuteness of the modern physician to say that he has learned nothing from the clinical observations (and mistakes) of such assiduous workers as Litré (1704), Baillie (1793), Abercrombie (1832), Cruveilhier (1835), Rokitansky (1839), Günzburg (1852), Virchow (1853), Mueller² (from Mueller, the empiric, clinical term "corrosive action" of gastric juice has descended), Panum (1862), Pavy,³ Axel Key,⁴ Ziemssen,⁵ Schleip,⁶ Leube,⁷ Riegel,⁸ Wilson Fox,⁹ von Noorden (1890), Stockton (1893), Fenwick (1893), Koch,¹⁰ Einhorn,¹¹ Leube and Mikulicz (1897), Hemmeter (1902), Ewald,¹² Dieulafoy (1902), Sellards,¹³ S. Möller,¹⁴ Westphal and Katsch,¹⁵ Rosenow,¹⁶ Mayo,¹⁷ Bolton,¹⁸ Spencer, Meyer, Rehfuß and Hawk,¹⁹ Cannon,²⁰ Carlson,²¹ and others.

As a possible excuse, it may be adduced that the older clinicians have neglected to put into practice the

facts developed respecting gastric physiology during the past decade, and that the knowledge accumulated by the modern group of clinical-experimental workers has not yet been "driven home" or become sufficiently available to general practitioners or the laity. Further, the healthy skepticism respecting experimental and clinical data, common to properly trained physicians, has prevented such physicians from glibly and boldly sending forth unqualified statements regarding actual causes of peptic ulcer and definite numbers of cases in which cure has been effected. The modern clinician holds a broader etiologic view of peptic ulcer than it is possible to inherit from study of ancient writings. He demands definite clinical proof that peptic ulcer exists before he institutes "ulcer regimen," and, should such regimen be carried out, he is properly cautious in his interpretation of his "cures." To him, relief of symptoms does not mean "cure," as it is common knowledge that of uncomplicated peptic ulcers (i. e., nonhemorrhagic, nonperforating, nondeforming or stenosing), 84 per cent. exhibit that peculiar, characteristic "periodicity" which, to the careless or the ignorant, indicates "cure." Along with Mayo, Crispin and others, I have frequently pointed out that without so-called "ulcer symptoms," and in stomachs whose secretion is acid-pepsin free, peptic ulcers are often found to be histologically unhealed, and may be the sites of most serious complications.

Until a few years ago, the treatment of peptic ulcer, particularly by nonsurgical procedures, was based mainly on the conception that peptic ulcers are caused, or if they have already formed, are aggravated, by the so-called "corrosive action" of acid gastric juice. This conception of the etiology of peptic ulcer has been so persistently emphasized by clinicians that it has obtained a widespread acceptance among practitioners in general. It thus follows that the medical mind almost universally, and frequently automatically, connects peptic ulcer with "corrosion," particularly "acid corrosion." With such conception of the origin of peptic ulcer, the therapeutic corollary that "acid corrosion, being the cause of peptic ulcer, indicates simply counteraction of acidity by alkali; prevention of corrosion follows and, hence, ulcer cure results" has required but mild cerebral activity in order to admit of its acceptance as a regimen of treatment in ulcer patients. With so simple an explanation of the etiology of a widely prevalent and grave ailment, it is not to be wondered, therefore, that among general practitioners (and, indeed, among clinicians who are more favorably located with respect to scientific investigation) the assumption that acid gastric juice is necessary for, and vital in, the production of peptic ulcer; that commonly in ulcer, acid is above "normal" titration values, and neutralization of this "hyperacidity" leads to cure of ulcer, has had a vogue not warranted by experimental, laboratory or clinical facts.

It is not necessary to point out to an audience of this character and experience that experimental investigations have failed almost uniformly in attempts at producing peptic ulcer by the introduction of acid of high titration values into the stomach. These observations have been made by investigators of such standing as Pawlow, Carlson, Ivy, Smith and others. If the gastric mucosa has been previously undamaged, and if the stomach is bile free, there may be introduced into the viscus free hydrochloric acid, other

inorganic acids or organic acids of a strength greater than ten times that of the acid titration values found in gastric ulcer stomachs or, in stomachs of persons free from gastric complaint or a pathologic condition, without peptic ulcer resulting. It has also been emphasized by Carlson that in persons who are affected with proved gastric ulcers, hydrochloric acid of five times as high titration value as that of the so-called "normal" gastric juice may be introduced into the stomach without discomfort clinically, without retardation in healing of the ulcer, or without the production of new ulcers. It has also been shown by numerous clinicians who have studied ulcer patients during the period of quiescence of their "ulcer symptoms" that, in such cases, the acid values of the gastric juice are frequently much higher than are those in the so-called "normal" gastric juice, or are greater than the values reported when the patients were experiencing dyspepsia, clinically. Such observations respecting increases in gastric juice acid values are especially liable to be recorded in the cases of those ulcer patients who have been treated by the continuous, "rule of thumb" and century old "alkalization" regimen, in which event, provided the careless and uncontrolled exhibition of great amounts of alkaline drugs has not caused complete mucoid and permanent degeneration of the acid-secreting cells of the stomach mucosa, the end-result is a delayed, and commonly increased, production of acid gastric juice. Without any painstaking research, clinical reports are available in which peptic ulcers have appeared and have progressed steadily to the point of exhausting hemorrhage or fatal perforation, while gastric juice acidity has been constantly below the so-called "normal," or even has been entirely absent. It is difficult to surmise how, in this type of patient, peptic ulcer could have been caused or its progress could have been accelerated as a consequence of so-called "corrosive action" of gastric juice.

From the histologic standpoint, so-called "corrosive effects" are most readily shown in that type of extensive, chronic peptic ulcer which is undergoing "malignant transition." In this class of case, the local changes in the gastric mucosa in every way represent the irritation effects one might theoretically ascribe to "acid corrosion"; and yet the gastric juice from such patients when analyzed quite regularly exhibits low, or an absence of, free hydrochloric acid. In the true peptic ulcer ("round ulcer" of Cruveilhier, not the accidental, self-healing "mucous erosion"), such irritation reactions about the ulcer, as might be expected of "corrosion" (and, indeed, are present when the gastric mucous membrane is traumatized to the point of true corrosion by acids, experimentally), are entirely absent. It has further been proved by an army of investigators, notably Rehfuss and Hawk, that the acid values in individuals gastrically well fluctuate in wider ranges than they do in patients with proved peptic ulcer, and in instances when, theoretically, it is carelessly assumed that the acid caused the ulcer or prevented its healing. It is common clinical knowledge that less than forty-eight hours after surgical or other trauma to the stomach wall (resection of ulcer locally, resection of portion of the stomach, gastro-enterostomy, etc.), acid values of the gastric juice begin to increase; and (with the possible exception of the gastro-enterostomized patient), within six months after extensive, local

gastric traumas, the acid values in the stomach are within or above the "normal" values. However, usually patients do not experience return of their peptic ulcers, establishment of ulcer at the site of surgical trauma or crops of new ulcers, consequent on "acid (or acid-pepsin) corrosion."

Etiologically, with respect to ulcer, it is an important observation that, following operations on the stomach, although the acid and peptic values of the gastric juice are steadily rising, healing and regeneration of the mucous membrane are not interfered with. To those who have had any sort of surgical experience, it is not necessary to mention that, should the patient die from an ailment not connected with the operative field, following extensive gastric resection, it will be seen that union has taken place in all layers of the stomach wall, that a new mucous membrane has formed, and that very slight local evidences of surgical trauma are to be noted. Such healing may occur in so short a time as a few weeks. Thus, it is proved that in man (not a "laboratory animal"), extensive loss of epithelium may be rapidly compensated for by the development of a new mucosa, even though the surgical area being repaired is more or less constantly bathed in that acid gastric juice which, empirically and purely, theoretically, is commonly assumed to possess "corrosive" qualities toward injury or partly devitalized gastric epithelium. These observations are of greater value than are data shown by experiments in ulcer production, because not only is one dealing with problems in human physiology and histology, but he has at hand observations of patients who exhibit those constitutional faults that have already permitted demonstrable, local gastric defects.

Knowledge of normal gastric physiology and histology should teach that such rapid and gross gastric repair as cited is not anything remarkable. From shortly after birth, the gastric lining is accustomed to resist injury and to make proper repair in the presence of a secretion rich in free hydrochloric acid and pepsin. Such secretion is the normal habitat of the mucosa of the stomach, just as in the mouth, pharynx and upper esophagus the normal habitat in which epithelium functionates is alkaline. Certainly, it ought not to be expected that when, artificially, the reaction of the secretion in which gastric epithelium has to live and functionate is changed from acid to alkaline, the condition is rendered more favorable to function or to repair after injury. It is a well known fact that, if the secretion of the mouth and the upper esophagus is changed from alkaline to acid, epithelial cells have great difficulty in maintaining proper protection and function—indeed, such change in reaction is not infrequently followed by visible, local evidences of destruction ("pyorrhea," erosions about the teeth and on the tongue, and erosive, bleeding, superficial or deep ulcerations in the pharynx or in the esophagus). When peptic ulcer exists, it is, therefore, a matter of serious question whether the introduction into the stomach of sufficient alkali to neutralize hydrochloric acid is not injurious rather than beneficial: the ulcer apparently heals in spite of excess alkali. The injurious effects of "continuous alkalization" would doubtless be more evident were it not the custom of such clinicians as practice this empiric form of therapy to make frequent gastric lavage a routine phase of their regimen. In this way, much of the excess alkali is washed

from the stomach, with consequent relief to the gastric cells, which have been caused to overfunction in their attempt to neutralize excess alkali and to restore an intragastric habitat normal, chemically. Hamburger²² has shown, however, that the exhibition of alkaline salts, e. g., sodium chlorid, etc., has (provided their concentration is sufficiently high) the power of limiting peptic activity. Hamburger's experiments are worthy of consideration, even though they may be few in number and performed chiefly *in vitro*. On the "pepsin inhibition" basis, Hamburger partly explains away the significance of so-called "corrosive acid action" with respect to production or aggravation of ulcer. Apparently, he assumes that if pepsin is rendered inert by the exhibition of alkali, then acid-pepsin combination, with supposed consequent "corrosion" or "digestion" of injured gastric mucosa is, in certain circumstances, limited. Hamburger's experiments, however, do not explain why, after surgical or other traumas of the stomach, when acid-peptic values soon become practically normal, repair of extensive damage goes on without interruption, and a normal mucous membrane is formed, or, at least, a mucous membrane results which is capable of protecting the deeper layers of the stomach wall, even though it may not maintain complete preoperative, secretory function.

Clinically, our own laboratory investigations in 2,168 definitely proved and not "clinically surmised" cases of peptic ulcer have revealed these facts: Of this number, fifty-six patients, 2.6 per cent., had gastric contents containing no free hydrochloric acid; 499 patients, 23 per cent., had free hydrochloric acid values below 30; 890 patients, 41 per cent., had free hydrochloric acid values within the normal range (40 to 50, Töpfer scale) and in 723 patients, 33.4 per cent., the free hydrochloric acid values were greater than the so-called "normal." The significance of these figures with respect to acidity in definitely proved ulcers adds further emphasis to the observations of Rehfuess and Hawk. These investigations show that in no form of gastric disease can the acid values be considered as indicating the causative factor of the disease, or that such acid variations are consequent on that disease; that, in health, the range of acid values in gastric juice is wider than is that of any of the values which formerly were supposed to be indicative of, or consequent on, gastric malfunction. Both low and high gastric titration values may be returned irrespective of gastric symptomatology. Even when fractionally estimated, the variations in gastric acidity, in both health and disease, can be regarded as incidents in gastric function. Frequently, they are only of ephemeral significance. Numerous observations made on the same subject, or numerous examinations of patients known to be affected with similar diseases, show widely varying differences in gastric juice acid values. These fluctuations, quite commonly, are irrespective of symptoms and the clinical and histologic course of the disease. Doubtless, they furnish only useful hints respecting the ability of stomachs to accommodate themselves to transient upsets or to abnormal functional demands of long duration.

About ten years ago, I became convinced that any treatment of "peptic ulcer" based on a fluctuating

22. Hamburger, W. W.: The Inactivation of Pepsin by Sodium Chlorid, *Arch. Int. Med.* 16: 356 (Sept.) 1915.

gastric chemistry was (as Leube, Rokitsanski, Riegel and others had shown, more than a half century ago) little more than guesswork, was unscientific, was not justified by any known published records and might, in fact, prove harmful to patients. My experience with abundant material has since confirmed my early opinion. Difficult as it sometimes is to discover the precise etiologic factors interplaying in ulcer patients, still, I am convinced that careful search for such factors will commonly disclose information which is useful and of great service in the establishment of an intelligent therapeutic regimen. In other words, search for etiologic factors in peptic ulcer indicates careful analysis of the individual patient, and signifies that the major part of the treatment is to be directed toward the individual patient who has the ulcer, with consequently a minor degree of treatment to the ulcer, which forms a small part of the patient's entire make-up. Such a regimen of treatment is not often a rosy therapeutic pathway. It means that masses of people cannot be moved about and worked on by inexperienced interns, nurses or assistants; it means that routine prescriptions for pills and powders are useless, and it means that so-called

ETIOLOGIC-THERAPEUTIC CLASSIFICATION OF FIVE
HUNDRED AND TWENTY-TWO CASES OF
PROVED GASTRIC ULCER

Group	No. of Cases	Per Cent.
1. Infections (chronic and acute).....	173	33.1
2. Arteriosclerotic (with vascular hypertension, 56 cases; without vascular hypertension, 21 cases)...	77	14.7
3. Visceral hypertonia (vagus or splanchnic hyperfunction).....	68	13.0
4. Chronic anemia (so-called "chlorotic").....	61	11.3
5. Syphilitic.....	41	7.8
6. Visceral hypotonia (vagus or splanchnic hypofunction).....	27	5.2
7. Postoperative.....	27	5.2
8. Industrial intoxication (occupational poisonings)...	22	4.2
9. Metabolic dysfunction (thyroid, suprarenal, pituitary, etc.).....	18	3.4

"diets" cannot be dubbed "first week," "second week," etc., ad infinitum, till the patient breaks away from his gastronomic chains, commits an "indiscretion in diet," "relapses," and comes back again to his powders, pump and pap.

ANALYSIS OF FIVE HUNDRED AND TWENTY-TWO CASES

With the purpose of further emphasizing the necessity for considering clinically the significance of etiologic factors in the treatment of peptic ulcer, and with the object of demonstrating the need of strict individualization in any ulcer regimen, I have carefully analyzed 522 gastric ulcers. These ulcers were proved actually to exist by objective data, namely, from surgical, roentgen-ray and pathologic studies. I do not consider it worth your time or my effort to make an inquiry, purporting to be scientific, into any group of ailments diagnosed "peptic ulcer" on only clinical history, physical examinations or testmeal evidence. The unreliability of data of such type is shown by the observations made in our clinic that only 53 per cent. of patients with gastric ailments who come to us with a diagnosis of "ulcer" prove to be affected with that disease when subjected to thorough clinical study. The remaining 47 per cent. of patients were affected with lesions of the gall-bladder or the appendix, simple gastritis, carcinoma,

syphilis, cardiorenal upsets, tuberculosis, alcoholism, occupational intoxications and forms of neurologic hyperfunction, i. e., vagus hypertonia.

The results of our studies enable me to present an ulcer classification based on what I consider valuable facts, etiologically, in ulcer causation, and to offer such grouping as a guide to intelligent, therapeutic management of peptic ulcer. It is granted that my classification is not complete: indeed, its first revision may come from me. However, my grouping carries essential pointings, therapeutically, and it gets away from the ancient, unproved and prevalent conception of peptic ulcer's being a local, gastric disease caused by so-called "acid corrosion." It also emphasizes the fact that gastric ulcer is rarely a disease due primarily to a gastric upset, but that the gastric lesion is only the local, accidental manifestation of a systemic disturbance, initiated by a great variety of agents.

There is not now sufficient time to submit details respecting the data entering into cases making up these groupings; such consideration is reserved for later reports. To the seriously inclined student of peptic ulcer and its clinical management, the classifications which I have given will, I feel sure, prove of value and will furnish significant hints respecting amplification of the individual groups and of the classification as a whole. To such practitioners as have not the opportunity or the inclination for extended inquiry into the therapeutics of gastric ulcer, my remarks and my classification of 522 proved ulcers will, I hope, result in a critical scrutiny of reports respecting the "cure" of ulcer by measures which have as their object the altering of intragastric chemistry only by medicines or diets, or of measures which purpose to alter a constitutional or metabolic fault by surgical removal of ulcer or a great part of the stomach. Local treatment of such gastric anomaly can give promise of permanent success only when coordinated with therapeutic measures tending to restore to normal the systemic disturbance of which the gastric defect is but a part.

1002 North Dearborn Street.

SURGERY OF THE THYROID*

JOHN F. BARNHILL, M.D.
INDIANAPOLIS

The most plausible theory of the causation of goiter is that it results from infection. Recently, many observers have believed that the infection is in part autogenous. In this connection much attention has been directed to the focal centers of infection in the adenoid, teeth and tonsils. While no direct pathway of travel for such infection from the throat to the thyroid has been proved, it has been assumed on clinical grounds that some such pathway exists. Many physicians contend, therefore, that thyroid disease may arise in the throat, and be perpetuated from this source. A clinical study of many goiter cases in connection with infection foci of the throat and mouth furnishes abundant evidence in support of this theory.

The intimate relationship between the larynx, trachea and thyroid gland is common anatomic knowledge. In health the gland lies on the upper trachea, often

* Read before the Section on Laryngology, Otology and Rhinology at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

extends over the cricoid and thyroid cartilages, and is closely bound to them by connective tissue. The recurrent laryngeal nerves are closely associated, and the normal blood and nerve supplies have much in common.

In disease of the thyroid this intimacy of the enlarged gland to the upper air tract is usually much increased, resulting in a multiplicity of symptoms, chiefly respiratory disturbances. Thus an aberrant goiter at the root of the tongue or within the trachea causes distressing dyspnea; a circular goiter may constrict the trachea even to a fatal degree; nodular goiters may compress the adjoining air tract sufficiently to cause difficult or dangerous respiration. Large colloid or cystic goiters result in varying degrees of respiratory obstruction, and by backward extension may interfere with the function of the recurrent laryngeal nerves, with the result of vocal disturbances varying from slight hoarseness to complete aphonia. Great thyroid enlargement also stretches the pretracheal muscles, and ends in their atrophy and final loss of function, which no doubt adds to the loss of vocal power and normal respiration. To the foregoing symptoms other almost innumerable ones may be added, most common among which are asthma, dysphagia, globus hystericus, great apprehension and neurasthenia. Indeed, many cases, especially of nontoxic goiter, produce more symptoms referred to the throat than elsewhere, and nearly all goiter subjects present some symptoms that are referred solely to the throat.

In view of this relationship of laryngology to disease of the thyroid body, and of the fact that the growth of laryngology has been in the direction of cure by surgical methods, the assumption to surgery of the thyroid on the part of the laryngologist may seem most natural, and perhaps may ultimately prove helpful.

ESSENTIAL POINTS IN DIAGNOSIS

Satisfactory results in surgery have always borne, and no doubt will continue more and more to bear, an inseparable relationship to diagnosis. Successful surgery of the thyroid must be bound, especially in certain types of thyroid, with the most accurate diagnosis possible of the actual condition present in the given case.

Modern operative technic, coupled with surgical training and skill, have reduced the mortality of goiter surgery almost to nothing; yet the mere fact that goiter operations may be performed in great numbers with almost no mortality does not necessarily mean that all patients who have been operated on have fully recovered health or have attained a satisfactory degree of improvement, or any improvement at all. Any discussion, therefore, that may lead to a better preoperative knowledge is still desirable.

Plummer classifies goiters into nontoxic, toxic-nontoxic, exophthalmic, and malignant. Nontoxic goiters are very plentiful and usually easy of diagnosis, and the relationship of diagnosis to the successful surgery of this type has comparatively slight importance. Many nontoxic goiters are undoubtedly not cases for surgery, especially if moderate in size and symptomless, as is frequently the case. When large colloid or cystic they may continue apparently harmless, although not infrequently pressure symptoms on the trachea and larynx may develop that give great anxiety to both patient and friends. The latter cases

may furnish complex problems of diagnosis, not, to be sure, as to the presence of a goiter, but certainly as to the safety of operating, depending on the amount of damage to the trachea and larynx, and to the circulatory and nervous system.

According to Plummer, already quoted, about 1 per cent. of all goiters at some time become malignant. The essential point to determine in cases of suspected malignancy of the thyroid is whether or not the disease is still confined within the glandular capsule; for if extracapsular thyroid malignancy has already taken place, operation would ultimately, if not immediately, fail to cure. I know of no present plan to determine with certainty the presence of malignancy in its earliest, and therefore the period of its intracapsular confinement.

It is not, however, with the foregoing classes of goiter that the chief concern in diagnosis is felt by the surgeon. Both thyrotoxic and exophthalmic goiters present preoperative problems that have not been solved with entire satisfaction. In the first place, there are undoubtedly plenty of cases that have well marked, exceedingly dangerous and troublesome thyrotoxicosis with no enlargement, or but slight enlargement of the thyroid gland. This fact needs repetition and emphasis. These cases are accompanied by pronounced nervous symptoms, tachycardia and loss of weight, and even to the casual observer the patients seem seriously ill; but since they may not have the one symptom of goiter that we most expect, namely, an enlarged thyroid, the origin of the disease may be, and indeed often is, overlooked. Such cases are sometimes diagnosed hysteria, neurasthenia, heart disease or nervous prostration. The patients are given nervines, tonics, rest, diet or change to seashore or mountain, usually with only temporary relief and most often with complete failure. The surgeon in such cases often needs the help of the thoroughly trained modern diagnostician. Together, a diagnosis will be made. Together, it will be determined whether or not the case is purely medical, wholly surgical, or both medical and surgical; and, if operation is indicated, the choice of time can best be determined.

The classical symptoms of thyrotoxicoses have long been known. It is only recently, however, that attempts have been made more definitely to interpret some of these for the benefit of surgery. For instance, it is an old observation that these patients lose weight. It has been the belief that if the rate of weight loss could be measured with accuracy, the information thus gained would show the severity of the toxic state at any given time, and thus not only be helpful to a diagnosis of the fact that the thyroid is the seat of the disease, but also furnish a reliable guide as to when, and when not, to operate. I refer to the metabolic theory as applied to thyrotoxicoses. When accurately carried out, it is stated that early and borderline cases of toxic thyroid states may be accurately diagnosed, and that indexes of safety and of proper time of operation are thereby furnished with an almost invariable certainty.

The value of metabolic tests is based on the fact, already established, that in all cases of thyrotoxic goiter, body waste is going on to excess, the degree of excess being in proportion to the severity of the toxic state of the patient. That is to say, if the goiter is mild, it will be found that the metabolic rate is low; whereas in severe types, especially during crises, the

metabolic rate may rise to twice the normal. Metabolic measurement becomes, therefore, according to its advocates, of first importance in diagnosis, especially in that class of cases that exhibit well marked symptoms of toxemia, but in which the goiter appears, from every objective method of testing its size, to be but little or not at all enlarged.

In borderline cases, McCaskey also employs the alimentary hyperglycemic test, and believes he has proved it of great value. This test is based on the fact that in normal, fasting patients, 100 gm. of glucose taken shows its peak of glucose in the blood before one hour, whereas in the toxic goitrous cases the crest of the hyperglycemia after an equal ingestion of glucose is not reached under an hour and, according to McCaskey, may continue to rise to the end of the second hour. Laboratory tests, when perfected, as they undoubtedly will be, will simplify the goiter problem, and will add much to operative safety, satisfactory as this at present is, of thyroid surgery.

Surgery of the thyroid assumes that all proposed surgical patients have been tested by every known and useful method of examination; that the type of case is accurately determined, and that the degree of toxicity is ascertained by laboratory methods, or is assumed to be some definite amount, the assumption without laboratory aid being based, of course, on the surgeon's operative experience. It is further assumed that all cases belonging to the purely medical group have been entirely eliminated from surgical consideration. When the patient is thus properly classified and differentiated, the surgeon has before him a much simplified and a much safer problem. His task is then one largely related to the anatomy of the neck and the execution of a modern surgical technic pertaining to a major operation.

IMPORTANT FACTORS IN THYROIDECTOMY

Any description of modern thyroidectomy is unnecessary here. Certain points and principles of the operation necessary to its successful performance will, however, always be proper subjects for discussion. My comparatively small experience leads to the belief that the following points are of greatest importance. One item conducive to success in thyroid surgery is psychic. No other factor helps better to withstand the operation than does full confidence of the patient in the surgeon. Such confidence establishes and maintains a tranquility of the greatly weakened nerve energy and circulatory power that is entirely essential to successful surgery in the severely thyrotoxic.

1. *Selection of Time for Operation.*—When once the definite diagnosis of surgical goiter has been made, the operation should be performed at the earliest period of safety. When is this period? In all nontoxic goiters, unless some other disease is present, which of itself would contraindicate any surgical procedure, the goiter may be removed when the patient is ready and is surgically prepared. In toxic and exophthalmic cases the patient's vitality may have been so wrecked by the toxic state that long preparation is essential before operation may be performed with safety. The time must in these cases depend, therefore, much on repeated physical and laboratory examination and, to some extent at least, on that surgical judgment which large experience alone makes reasonably reliable. Rest, both mental and physical, to overcome the increased metabolism is essential. Rest is often diffi-

cult to secure. Rest in bed at home with the family obligations all about is not always helpful rest. Even in the hospital attempted rest fails in many instances, the patient grows peevish, and the toxic state becomes worse. In such cases if the metabolic rate can be reduced to one-third above normal, and the pulse rate below 120, probably the safest time for operation has arrived. Many of these patients feel that a prolonged period of preparation is of itself injurious to them, and they sometimes appeal for early surgical relief. Under such circumstances, operation, either ligation or thyroidectomy, is, I believe, usually advisable at that time.

2. *The Anesthetic.*—Experienced goiter operators hold different views concerning the best and safest anesthetic for thyroidectomy. In the Kocher clinic, where the number of patients is large, a local anesthetic is advocated and used. The elder Kocher believed this plan safest and was influenced somewhat because he believed that by its use he could best protect the recurrent laryngeal nerve. I have seen him perform many goiter operations under local anesthesia. The patient walked both in and out of the operating room. He was requested to use the voice during that part of the operative procedure when the nerve was approached, in order to inform the operator whether or not the recurrent nerve was injured, or was likely to be injured. Most of the patients whose operations I witnessed complained considerably of pain, especially when the goiter was luxated or dragged on. It has not been proved that the anxiety and pain experienced during this operation under local anesthesia do not cause as great harm to the patient as does the general anesthesia, if not even greater harm.

Crile probably has been the leading advocate of nitrous oxid and oxygen anesthesia. He has had many satisfied followers. When administered by an expert, this form of anesthesia has much to commend it. One operator has said that it is probably not safer than ether, but is certainly saner than ether. The Mayos are prominent among those who use ether almost exclusively. Aside from the unpleasant inhalation of ether at the beginning, and the almost certain nausea during recovery from it, ether is to me the ideal anesthetic in goiter surgery. It seems safest. It predisposes less to venous oozing, and it may be trusted to less experienced hands. One conclusion is evident, namely, that any one of the three methods may be safe and satisfactory, as evidenced by the large number of cases in which it has been used by its chief advocate. Much depends on the experience of the user. One may reasonably assume that the experience and training of the anesthetist counts for more in the safety and wisdom of the one or the other plan, than does the anesthetic itself.

3. *Minimum Loss of Blood.*—A great factor of safety lies in limitation of the loss of blood to the minimum. There is no disagreement among operators on this point, but its importance justifies repeated emphasis. Not much blood can be lost with safety, since the patient already is anemic, and therefore the drain of an amount that would be harmless in other classes of surgery would prove fatal here. Fortunately, with rare exception, limitation to a small loss is possible. With the patient properly prepared, in a modern hospital, with abundant light, proper assistance and adequate instrumentation, the question of loss of blood becomes one largely of surgical mechanics. It

seems not a little strange now that only a few years ago death from hemorrhage, and frequent, severe and dangerous hemorrhages, following thyroid surgery, appear to have been the expectation in all operations for goiter. It is evident why the mortality was then high. The splendid mortality of the present is no doubt largely due to the almost bloodless operation.

4. *Removal of Capsule.*—Argument, so far as I know, is at an end concerning the best and safest plan of conserving the function of the parathyroids and the recurrent laryngeal nerve. Safety to these structures depends on leaving that portion of the posterior glandular capsule which overlies the nerve and the parathyroid bodies. This is represented by the lower two thirds of the posterior portion of the capsule. I am convinced by my own experience that it is entirely possible, in some cases at least, to strip from the posterior capsule the parathyroids and thus remove the entire capsule. This is best done by working from the upper pole downward, and using a piece of gauze to do the stripping, always, of course keeping directly against the smooth, shiny glandular capsule and noting at all times that nothing is left on the capsule. The recurrent laryngeal nerve is by the same procedure insured from injury. I do not advocate the plan of entire capsular removal because the parathyroid bodies are sometimes embedded in the capsule, or even lie completely within the gland, and in such cases would of course be endangered or removed by the removal of the capsule. I simply make the point that I believe it may be safe.

5. *The Question of Ligation.*—When should ligation be done? How often is it necessary? Ligations are indicated only when the actual removal of a necessary amount of the thyroid gland is known to be hazardous. Since this extra hazard occurs in only two classes of goiter, the highly vascular and the severely thyrotoxic, it is evident that ligations are justified only when one of these conditions is present, and in the latter class only in case the metabolic rate is high, great exhaustion is present, tachycardia and arrhythmia marked and, in general, a state of collapse is imminent. In the highly vascular case, ligation greatly limits the amount of hemorrhage if operation is later attempted and often is of itself a sufficient method of cure. Kocher, though not the first to employ ligation in the cure of goiter, was the first to employ the plan extensively, and in properly diagnosed and carefully classified cases. Kocher pointed out the uselessness and even danger in ligations for the cure of cystic and colloidal goiter. In such cases, cutting off the blood supply to an already crippled gland, it is evident, may so lessen the production of thyroxin as to promptly result in myxedema. In milder thyrotoxic cases, while the surgical risk is yet good, ligation is helpful, but cannot be considered the best procedure, since thyroidectomy gives more permanent and curative results. Ligation is undoubtedly a most valuable, though a more or less temporary measure in dealing with the shattered thyrotoxic case, for it may be done when the greater operation of resection would prove fatal. Ligation of both upper poles after the plan of Stamm and Jacobson is rapid and safe, and the results are often astonishingly good. It is a common observation that after proper ligation the pulse rate falls, tachycardia subsides, sleep is induced, appetite improves, and altogether the vitality, which had reached the danger point, is revived. In severe exophthalmic goiter, Plummer estimates

that ligation reduces the metabolic rate about fifteen points in the succeeding eighteen days, which, of course, greatly lessens the hazard of the final thyroidectomy.

Improvement following ligation does not usually continue to the point of final cure. After a varying time the blood and nerve supply to the gland, which was partially cut off by ligation, is more or less restored, and then the former hypertoxic state sets in again. Before this period arrives complete thyroidectomy should be done provided it is reasonably safe.

Many opinions have been expressed as to which thyroid vessels should be ligated. In my few cases I have ligated only the upper poles, the ligation requiring only a few minutes under a local anesthetic, and being painless and shockless. To ligate the lower thyroid vessels is nearly as difficult as the resection of the gland, and hence the complete operation should be chosen rather than inferior ligation. With the improved technic of today, and with proper preparation of the patient for operation, the use of ligation becomes increasingly limited.

6. *Extent of Removal.*—One of the most important questions the surgeon must settle as he proceeds with the thyroid operation is, How much of the diseased glandular stricture should be removed? On this decision either cure or disaster may depend. One writer says that a portion as large as a hen's egg should be left. Another thinks a remnant as large as a walnut should be left. A third believes that since the normal thyroid gland weighs from 20 to 30 gm., this amount is sufficient to leave. Still others say that one fifth or even one tenth of the whole should be left. So many opinions give the impression, which is probably correct, that nobody knows exactly how much to leave, for it must be true that each case is different, and therefore an amount which would be more than should be left in one case might, if taken as a standard for another, result in hypothyroidism. If the gland is cystic or colloidal, and much of the normal secreting structure is impaired, the removal of so much as nine tenths would probably be hazardous. In hyperplastic, thyrotoxic or exophthalmic goiter it is conceivable that four fifths or even nine tenths of the gland might safely be removed. Like many other problems in surgery, the question of how much to remove is one that must be settled during the operation, after the gland is exposed and when the extent of its pathologic condition may be more or less accurately determined. On this point the question is one that must be determined by the surgeon's own judgment and experience. It is neither easy nor safe to follow those who say leave a stated proportion, for it is evident that to do so, to estimate such an amount with any degree of accuracy during the operation, could not be done. Another factor also enters into the question, namely, the degree of lost function in the gland resulting solely from the greatly lessened blood supply incident to the thyroidectomy. One upper and one lower pole is almost certainly ligated, and not infrequently both upper poles are blocked. To underestimate the future effect of these ligations, and therefore to remove a maximum portion of the thyroid, just as though the portion removed constituted the entire change in the secretive power of the gland, might end in disaster. It would seem wise, therefore, certainly safer always to err on the side of leaving too much rather than too little of the gland.

Of course this advice, if followed, will sometimes result in the necessity of secondary operation; but if so secondary operation may be justified on the ground that it is possible to cure hyperthyroidism, whereas hypothyroidism as a result of excessive surgical zeal is not amenable to surgery.

7. Lobectomy Versus Translobular Resection.—Another point, although more of esthetic interest than of surgical value, relates to the question as to whether the operation should consist of a lobectomy, partial lobectomy, or of a translobular resection. Of course the question largely settles itself in cases in which only one lobe is involved. Some years ago, operators almost invariably performed a more or less complete lobectomy even though the opposite lobe also was enlarged, though to a less extent. Gradually the tendency has been to perform an operation that will leave the neck symmetrical, and it is obvious this cannot be done unless surgical consideration is given to all the lobes. Lobectomy has its advantages. It can be more quickly done. Less loss of blood attends lobectomy, and less oozing of blood and serum follows during the first few days. Since either lobectomy or translobular resection is equally safe if preformed with an equal degree of skill, and since the curative result is exactly the same, the foregoing points in favor of lobectomy are not good argument for its performance; for whatever the final result as to cure of the patient may be, if the patient's neck remains deformed, disappointment to the patient and to friends is certain to follow.

PERSONAL EXPERIENCE

My personal operative experience is based on 150 cases. Compared with that of others, this small number would not justify a report were it not that my observations are made somewhat from the point of view of the laryngologist rather than from that of the general or abdominal surgeon.

I have had no death that was in any way connected with the thyroid operation; one death occurred more than three months afterward, and was due to recurrence of the hyperthyroidism. The patient, a woman, aged about 30 years, had in extreme degree the symptoms of hyperthyroidism with enlargement of the right lobe of the thyroid. After resection of this lobe she was greatly improved and returned home in two weeks. Unfortunately, her whole family was of that class which feels the imperative necessity of constant bedside presence, and of visible expression of apprehension. Attending physicians were of the belief that this attitude of the family was largely responsible for the fatal result.

The lack of mortality in my cases is perhaps in part due to the fact that 80 per cent. of all my cases have been nontoxic goiter, and of these nearly all the earlier patients had enlargement only of the central lobe. These patients were nearly always in good health except for pressure symptoms and nervousness. Such cases are good surgical risks, and hence if thyroidectomy is performed according to the principles of modern surgery, the percentage of recovery should be near 100.

My first thyroid operation was in February, 1890. The patient was 16 years old, and was in perfect health except for a choking sensation due to the presence of a pretracheal tumor as large as a pullet's egg, which on removal proved to be an enlargement of the thyroid isthmus. At that period solutions of mercuric chlorid were used in all operations, and were freely used in the removal of this goiter. I recall that much bleeding was encountered and that mild infection followed, even though accepted antiseptic precautions were employed. The operation was performed outside a hospital. A good recovery took place, but with more scar than follows present procedures.

In August, 1896, I examined a Miss —, of Centerville, Ind., who complained of difficult respiration and sensations of choking. There was no external tumor, but when the tongue was depressed deeply a large bluish mass could be seen above the epiglottis. The woman was 40 years of age, and I suspected malignancy of an enlarged lingual tonsil. After several examinations covering a period of two or three weeks, there seeming no evidence of malignancy, I succeeded in passing a large wire loop over the growth and in removing it gradually by snare. It was larger than an English walnut, thickly traversed by veins, and slightly lobulated, though smooth. It proved to be thyroid tissue, evidently an aberrant thyroid. The distressing symptoms were relieved, and there was no evidence of return several months later, after which time no further information was received.

Three cases were for large abscessed thyroids. Two of these were in women recently confined, in which the breaking down of the gland was so extensive and advanced that the diagnosis could be made by the history of the cases and palpation of the tumor. My third case was that of a man about 35 years of age, a railroad fireman, who had carried a large goiter, which evidently was a simple hypertrophy, for many years. He had had what he stated was influenza in the fall of 1918, and, he alleged that the disease settled in his neck, causing him to remain in bed many weeks. When first examined by me there seemed an enormous, hard, bilobular goiter present, accompanied by fever, pain and stiffness of the neck. Abscess seemed almost certainly present. At operation both lobes were so thoroughly hollowed out by the suppurative process as to give ground for the thought that hypothyroidism might result, although until now no such symptom has developed.

In three instances, cartilaginous formations were encountered during the glandular resection. Under the finger one of these felt cylindric and corrugated. Had it not been for the fact that the object lay far external to the median line, and that the trachea could be outlined in its normal position, it could easily have been mistaken for the windpipe.

Only one patient has had any degree of vocal impairment. This was in the nature of a slightly "changed" voice, as she expressed it. On examination of the vocal cords, perfect movement was present and therefore no injury to the recurrent nerve had occurred. The vocal difficulty was due, no doubt, to the stiffness and temporarily impaired mobility of the accessory muscles of the larynx that were severed at operation. I have not seen this patient for a long time, and presume she now has no complaint.

One postoperative hemorrhage occurred. The patient, a man, aged 38, with large bilobular enlargement, was operated on at 2 p. m. by translobular resection, and the wound closed over a dry field. At 1 a. m. next day, the nurse reported that hemorrhage was taking place. The gauze dressings were wet, and blood had trickled into the bed. The neck was ballooned to an enormous size. The wound was immediately opened in the operating room, under strict asepsis. No anesthetic of any kind was used. The sutures of fascia and muscle had all pulled apart, and several ounces of blood clot filled the cavity. This blood clot was scooped out with the hands and inspection made for active bleeding points, but none were found, the entire wound being dry. The sutures were reinserted, morphin and proctoclysis were given, and an uneventful recovery followed. A general oozing evidently caused the trouble.

Four cases were partially substernal. No special difficulty occurred in operating in three of these, but the fourth, a man, aged 65, and stoutly built, presented numerous points of interest and danger. The thyroid was large, bilobular and of long standing. Gradually the left lobe had encroached on the trachea and larynx until at the time of operation the larynx lay under the angle of the jaw on the right side. Respiration was labored, and, when the patient sat quietly, could be heard 20 feet away. As a result, both heart and lungs were greatly impaired, and although he seemed resigned to a possible unfavorable outcome, there was harmful apprehension concerning it. In lifting the large substernal mass of goiter from its bed there were a few moments of anxiety because of intensely labored breathing, and several times it was felt wise

to drop back the substernal portion and allow the patient more air until such time as it might be wholly withdrawn and removed. The trachea was torn in one place. The rings on one side were partly absorbed and weakened, and this part of the trachea was finally supported by suturing to the pretracheal fascia and muscles. Some blood found its way into the trachea, giving rise to cough and bloody expectoration during the succeeding few days. Complete recovery occurred, the patient being better now after two years than at any time for a score of years preceding.

My remaining patients were thyrotoxic or exophthalmic, and included almost every degree of severity. I have felt that the safety of these, as shown by their survival of the operation, was due in great measure to trustworthy diagnosis and adequate preoperative preparation.

In only three cases was ligation necessary. Preoperative preparation in these failed, all thyrotoxic symptoms continuing throughout a prolonged period of rest and medication. One of these patients was in bed for three months, yet the pulse rate continued 130 when she was absolutely quiet, and would rise to 150 on slight movement. She was greatly emaciated, slept almost not at all, sweat profusely, and presented altogether a condition quite unfavorable to complete thyroidectomy. The two upper poles were ligated at the same operation under local anesthesia, with almost no disturbance to the patient. Appetite and sleep improved and the pulse rate fell as low as 68 within a week, remained below 90 for two weeks when it began to rise, and in eighteen days was 100. Complete thyroidectomy was safely performed at this time, and was followed by uneventful recovery. Within three months this patient was following an almost normal life. The other two ligations were satisfactory, but the results were not so striking.

RELATIONSHIP OF DISEASED TONSILS TO GOITER

Much interest has been shown by many operators in the relationship of diseased tonsils to goiter. Shurley, Tinker and others have written on the subject and believe that diseased tonsils are an important causative factor in most cases. In the last six years I have made accurate note as to the presence of diseased tonsils in all goiter cases. More than 90 per cent. of all cases that I have examined have had clearly evident disease of the tonsils, and judging them from the most modern point of view as to what constitutes a diseased tonsil, I think practically all may rightly have been classed as having foci of infection in the tonsil. In more than 50 per cent. of my cases of goiter in which operation was performed during this period, the tonsils were removed before the thyroidectomy, sometimes as long as a year previously, in the hope that the goiter operation might thus be avoided. It seems certainly true that after the thyroid is once diseased the removal of the tonsils has little appreciable beneficial effect on the thyroid disease. Indeed, I have seen the thyroid rapidly enlarge and the thyrotoxic symptoms increase after the performance of a most complete tonsillectomy. These observations do not, however, form a good argument against the possibility that the diseased tonsil may have been the original focus from which the thyroid received its infection. Indeed, the frequent presence of infected tonsils in thyroid cases points almost certainly to a connection between the two diseases; but the point I wish to make is that clinical experience seems to justify the belief that when the thyroid is once diseased, from whatever source, the removal of the tonsils has but little effect on the future course of the thyroid ailment, but does, of course, improve the physical condition of the patient, and that tonsillectomy is, therefore, to be recommended as a preoperative measure of great value.

FINAL RESULTS

A correct statement of the percentage of final cure in my series of thyroidectomies cannot be made. I have been in correspondence with, or have seen most of the patients months or years after the thyroidectomy. I know of no dissatisfied patient after two years. It is not unusual for thyrotoxic patients to expect a too rapid cure, and to resume early a mode of life that is prohibitive of complete cure. These usually learn from experience their limitations; and when they finally accept them, recovery takes place. Many toxic goiter patients find it necessary for economic reasons to return to some occupation at an early date. Such patients are often mothers with small children, and these feel the necessity of resuming household cares at once. Strangely enough, these mothers often recover under most trying environment. Of course, all nontoxic goiters are well as soon as recovery from the operation takes place. Exceptions must be made for those cases in which pressure has set up respiratory difficulties, and especially when the trachea has been severely damaged.

ABSTRACT OF DISCUSSION

DR. EMIL MAYER, New York: I wish Dr. Barnhill would tell us whether he omitted to read that part of the paper in which the differential diagnosis of the condition was made. The reason I ask is that quite recently I saw a patient who had been advised by a prominent surgeon to have an operation performed on her thyroid. She had no pressure symptoms, no tachycardia, nothing that would indicate the effect of a diseased thyroid, except a swelling of the neck. She was a young woman, and was naturally averse to having an operation performed that would leave a scar. To my mind she had no thyroid and required no thyroid operation, because it was simply a bronchocele. How frequently that occurs, perhaps, the essayist will be able to inform us. In this instance the patient made a very good recovery. The hypodermic needle evacuated fluid, and a few injections of iodine resulted in a cure with disappearance of swelling and no scar tissue.

DR. NORVAL H. PIERCE, Chicago: May I ask the essayist to tell us what constitutes a diseased tonsil?

DR. JOSEPH C. BECK, Chicago: I am somewhat disappointed in Dr. Barnhill's paper. While I hoped that he would say that he operated on the thyroid, my thought was that he would bring out the importance of the laryngologist's connection with surgery, particularly where he is indispensable, as when the patient has tracheal collapse from a large thyroid or when there is present a substernal or a subclavicular thyroid which makes operation practically impossible for the general surgeon. There is nothing better than to have the laryngologist see the patient before anesthesia is induced or before the operation is undertaken under local anesthesia, and with a tracheal catheter or a bronchoscope do an intubation before the operation is begun. You have all, perhaps, witnessed the dilemma in which the general surgeon finds himself when he attempts to operate in a case of substernal or subclavicular tumor. It is only for a short period of time, but long enough to put the patient in jeopardy. Another thing I hoped the doctor would bring out was the question of operating on the larynx and trachea in the presence of a large thyroid. We want men to take up borderline surgery. If we are claiming to do other operations on the neck we should know the anatomy, and if there is a condition of laryngeal and tracheal disturbance from the thyroid and it must be removed, it is a question of whether you wish to do it or not.

DR. THOMAS E. CARMODY, Denver: I have a patient who has a patent thyroglossal duct. Every time he has an attack of influenza he gets an infection of this duct with swelling of the thyroid. Recently, during one of these attacks, I succeeded in getting some of the pus from the duct. One of

our pathologists, after taking a culture, injected it into a rabbit. The rabbit was dead in forty-eight hours, and a very much enlarged thyroid gland was found.

DR. JOHN F. BARNHILL, Indianapolis: In answer to Dr. Mayer as to the differential diagnosis, I state in the paper that every possible means is used to differentiate these cases and to classify them so that by no possibility could any case that is not a surgical goiter reach the surgeon. I have received aid in difficult cases from the internist who is skilled in every feature of diagnosis, and thus have more certainly avoided overlooking any point in diagnosis that should not be overlooked. Some of these borderline cases are exceedingly difficult to diagnose. Dr. Pierce asked if I could tell when a tonsil is diseased. I would answer briefly: if we find the patient has an occasional sore throat, or a continuous sore throat, be the tonsil large or small, if we are able to express infective material from the crypts of such tonsils, if the tonsils are hypertrophied and appear sore, if there is a history of general aching, muscular soreness and stiff joints, if, in addition, the patient has pains in the neck, shoulders and back, then I think we may assume that the tonsils are diseased, and are a menace to health. If I understand Dr. Beck, he expects the laryngologist to stand by during thyroid operations performed by an abdominal surgeon, and to meet emergencies that may arise. It seems to me that since the laryngologist knows what these emergencies are likely to be, and has the apparatus for meeting them, that he, if properly trained surgically, should be equally competent to perform the thyroidectomy. During my earliest work I kept a tracheotomy set at hand that I might use, if necessary, but no occasion has ever arisen for using it, even in the substernal cases of goiter. A tracheotomy, when necessary in patients with thyroid enlargement, would be done exactly as a tracheotomy in any other case would be done. The trachea is cut down on, the isthmus of the thyroid is divided and retracted without difficulty, while, of course, all vessels are ligated as one proceeds. The enlarged thyroid would not add to the danger of the operation.

HEART DISEASE AS A PUBLIC HEALTH PROBLEM *

LEWIS A. CONNER, M.D.
NEW YORK

In presenting a plea for a wider recognition of the public health aspects of heart disease it is well to begin with an attempt to visualize, in some degree at least, the size of the problem involved. This is not altogether an easy matter, for it is obvious that neither statistics illustrating the incidence of the disease nor those showing the mortality from such disease will give a complete idea as to the importance and size of the problem. The economic aspects of the subject are clearly related to the degree of disability that the disease entails and the length of time that such disability is likely to exist. Accurate information on the latter points is not available, and I shall not dwell on this aspect of the subject now further than to remind you of the familiar facts that in patients suffering from disease of the heart a certain degree of physical disability often exists for a good many years, and that before death finally occurs there is usually a period of complete disability and dependence on others, which may extend from several months to several years.

If we turn now to the question of the incidence of heart disease and its mortality, we find at hand statistics that will enable us to form a fairly accurate judgment concerning the size of the problem. The figures of the local draft boards during the war show that

among the men of the country of military age the rejections for organic disease of the heart amounted to 30.74 per thousand. Of the men accepted by the local boards and subsequently examined at the camps by army surgeons, the rejections for heart disease averaged 11.56 per thousand. This brings the total rate of rejections for heart disease up to 42.3 per thousand, or 4.25 per cent. In other words, among 5,000,000 men of military age, more than 200,000 were disqualified for service because of heart defects. It is doubtless true that in these examinations a good many men with organically sound hearts were included among those rejected; but the error is offset, in part at least, by the fact that many men with the milder forms of disease of the heart were accepted for military service. In considering these figures it should be remembered that they fail to include two very important types of heart disease—that due to syphilis and that due to degenerative changes—which are only rarely seen in men of military age. Statistics from civil life are not easy to obtain. Almost the only ones available are those of results of the examination of applicants for life insurance policies, and these vary considerably in the different companies depending on the caution or liberality exercised in the acceptance of applicants with what seem to be minor heart defects. large and carefully managed companies, during the period from 1915 to 1918, the rate of rejection for heart defects was 24.4 per thousand, in spite of the fact that persons with the more obvious forms of heart disease are not likely to apply for insurance.

A report of the Department of Health of New York City, covering over 250,000 examinations made by school medical inspectors during the year 1918, revealed an incidence of heart defects among schoolchildren of 1.6 per cent. This would indicate that among the schoolchildren of New York there must be approximately 20,000 with evidences of some cardiac disorder.

When we turn to mortality statistics for information concerning the size and importance of the heart disease problem, we find some very interesting comparative figures. The accompanying table is taken from a recent instructive statistical paper on this subject by Mr. Frederick L. Hoffman, vice president and statistician of the Prudential Insurance Company of America. From this table it is seen that diseases of the heart were responsible for almost one eighth of the deaths of all ages and for almost one fifth of the deaths in persons of 40 years of age and over.

These various figures, then, give us some idea of the numerical size of the heart disease problem in the different age periods and show the affection to be one of the more common of the chronic diseases, even during childhood. They do not, however, necessarily prove that affections of the heart should be singled out

* Read before the Section on Preventive Medicine and Public Health at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

from many other common diseases as deserving of special attention from the standpoint of the public health. Indeed, the movement, which is now gathering headway, for the improvement and coordination of existing agencies for the relief of sufferers from heart disease and for arousing interest and cooperation in the problems of prevention has come into existence not so much because of the frequency of cardiac disease as because of the conviction that our present methods of dealing with the problem involve enormous economic waste and immeasurable suffering, much of which is unnecessary and preventable.

AGENCIES IN NEW YORK

It may be of some interest to review briefly the history of this movement so far as it concerns New York City. The initiative came from a small group of social service workers and hospital physicians who were much impressed by the lamentable need of facilities for the proper after-care of cardiac patients who had been discharged from the hospitals after more or less complete reestablishment of their heart compensation. In many instances the direct cause of the breakdown had been the laborious character of the work engaged in; and the two essentials for the preservation of their regained health—prolonged convalescent care and an opportunity to secure work of a less exacting sort—were nowhere to be had. The first tentative effort to remedy these conditions came in the establishment in 1911 of an outpatient heart clinic in Bellevue Hospital under the charge of Dr. Hubert V. Guile, and the success which attended this modest undertaking has been due to Dr. Guile's enthusiasm and perseverance and to the sound principles on which the clinic was based. It was held in the evening in order to secure the attendance of working patients. It included periodic examinations of all enrolled patients, no matter how well they might feel, and, perhaps most important of all, it had the services of an intelligent social service worker whose duties included the visiting of the patient in his home, the education of the patient and his family, the improvement of home conditions, and often the securing of some lighter or more suitable form of work. The results of the clinic in saving heart cripples from periods of decompensation and in enabling them to continue as wage earners have been surprisingly successful, and it has served as a model for the large number of dispensary heart classes that have since been opened.

In the following year (1912), an effort to solve this urgent problem was made along quite different lines by the formulation of plans which led to the incorporation of the Trade School for Cardiac Convalescents. This had for its object the maintenance of a country convalescent home, in which laboring men with crippled hearts could be given protracted convalescent care under favorable conditions and careful supervision, and at the same time could be taught a more suitable and less exacting trade. This arrangement, which was frankly an experiment, yielded much useful and interesting information. It showed that, under favorable conditions and supervision, such heart cripples could perform fairly laborious work for the greater part of the day, not only without injury, but apparently with actual benefit to their damaged hearts. Although this proved to be an expensive method of dealing with the problem, it served as a valuable object lesson to the larger convalescent homes, and was instrumental in opening the doors of these to a class of patients which

up to that time had been looked on as unsuitable for such institutions.

In the meantime, interest in the problem of the heart cases had been growing steadily, so that in 1915 the time seemed ripe for the formation of an organization which should deal in a comprehensive way with the various problems related not only to the care and relief of heart patients but to the even more important matter of prevention. The result was the incorporation of the Association for the Prevention and Relief of Heart Disease. The objects of this association, as defined in its first statement, were: to gather information on heart disease; to develop and apply measures that will prevent such disease; to seek and provide occupations suitable for heart disease patients; to promote the establishment of special dispensary classes for such patients; to extend the opportunities for adequate care of cardiac convalescents; to urge the provision of permanent institutional care for such cardiac patients as are hopelessly incapacitated for self support, and to encourage the establishment of associations with similar objects in other cities.

In the furtherance of these objects, a central office was opened and an executive secretary secured. It was felt that the first and most promising field of activity was the encouragement of the opening of special cardiac classes in the dispensaries throughout the city, modeled after that of Bellevue Hospital. The response on the part of dispensary physicians was prompt and cordial; the difficulty in most cases lay only in the securing of funds for the employment of a social service worker, without whose services, it was realized, the classes could not hope to operate successfully. In spite of this difficulty, our entry into the war found New York City with twenty or more of these cardiac dispensary classes in successful operation. For the period of the war it was found necessary to suspend the activities of the association; but a considerable number of the cardiac classes continued to function, in spite of the great dearth of physicians. The work of the association was resumed last autumn, and has rapidly gained momentum. Its accomplishments up to the present may be thus outlined:

1. The encouragement of the formation of special cardiac dispensary classes. At present twenty-seven such classes are in operation, in which some 3,000 heart patients are registered. Most of these classes are designed especially to care for working men, and for that reason are held in the evening. There are, however, among them eight classes devoted to the care of children with heart diseases.

In order to bring together the physicians engaged in the dispensary care of heart patients, there has been formed, under the auspices of the parent organization, an association of cardiac clinics, in which the special problems of these clinics are considered. As a result of these conferences, some progress has been made in standardizing the work of the clinics; that is, the classification of patients with respect to their degree of disability, the types suitable for treatment in convalescent homes, methods of treatment, etc.

2. The increasing of facilities for the care of suitable heart patients in convalescent homes.

Up to the time interest was aroused in the welfare of the cardiac patients, convalescent homes, almost without exception, discriminated against this class of convalescents. The much more liberal policy which has since been adopted by most of these institutions has been due largely to the example set by the trustees

of the Burke Foundation at their splendid convalescent home at White Plains. Here, under the wise and far-sighted policy of the director, Dr. Frederick Brush, convalescent heart patients, both adults and children, have been accepted in steadily increasing numbers, and have had the advantage of a protracted stay and of suitable occupational therapy. In all, more than 2,000 such patients have been cared for by this institution during the last six years, and the results in properly selected cases have been most gratifying. At present the convalescent hospital maintained by St. John's Guild is arranging to provide for 150 children with heart disease, and the doors of various other similar institutions have been opened to this class of patients.

3. The arousing of greater interest in the welfare of schoolchildren with heart disorders. It is recognized that the proper medical examination and supervision of children during school age offer exceptional opportunities, not only for the shielding of crippled hearts from further damage, but also for the prevention of the type of heart disease prevalent at that time of life. The association has given its active support to various efforts directed toward these ends, such as more frequent and complete physical examinations of schoolchildren, with special attention to diseased tonsils and teeth and to adenoids; greater protection in the schools for the heart cripples, and education of the parents, the teacher and the family physician as to the importance of tonsillitis, slight rheumatic and "growing pains," and as to the need of greater care during convalescence from the acute infectious diseases, etc.

The question of the desirability of the segregation of cardiac children in special classes in the schools is being given careful study. Through the cooperation of the board of education, this experiment is being carried out in several of the schools, under supervision by certain of the dispensary heart clinics; but it is yet too early to know whether or not the plan is deserving of general application.

4. The accomplishment of a good deal individually by the social service workers in the various dispensary heart classes, in the matter of providing heart cripples with more suitable occupation. During the last two or three years, however, a great part of this burden has been taken over by the Employment Bureau for the Handicapped, maintained by the Hospital Social Service Association. In this extremely difficult field of practical philanthropy this bureau has achieved notable success, partly no doubt because of the unusual demand for labor of all sorts, but chiefly because of the exceptional degree of intelligence, perseverance and tact displayed in the carrying on of the work.

PREVENTION OF HEART DISEASE

Progress in that phase of the problem which relates to the *prevention* of heart disease has, naturally, been slowest and least appreciable. This subject is so extensive and so many sided that a discussion of it cannot be included in this short paper. It seems evident, however, that efforts in this direction must follow the three lines which correspond to the three great causes of heart disease; namely, the prevention of rheumatic infection and its complications, the prevention of syphilis and its late effects, and the postponement of the degenerative changes incident to the later years of life. That the task is beset with difficulties does not justify us in failing to undertake it; rather its difficulties, as well as its size and its importance,

call on us the more loudly for a determined and sustained attack on it. Such an attack obviously demands concerted action on the part of investigators, clinicians and various public health organizations. It would seem as though the coordination of these various agencies could best be accomplished through a national organization formed on the lines of the Association for the Prevention and Relief of Heart Disease in New York City. There are signs in many parts of the country of an awakening of public interest in the heart disease problem. Special heart clinics are already in operation in Boston, Chicago and other cities, and the formation of a national organization dedicated to this object would seem to be the next logical step. The history of every national organization of similar character has shown the enormous gain in momentum that results from such coordination of effort and unity of purpose.

121 East Sixty-Second Street.

ABSTRACT OF DISCUSSION

DR. ALEXANDER LAMBERT, New York: In the prevention of heart disease neither sanitation nor inoculation will answer. It is a question of personal hygiene and education, and the disease when once acquired handicaps permanently. The great cause of heart disease up to the age of 30 is sepsis or rheumatism. Seventy-six per cent. of rheumatic children under 10 years of age have affected hearts. Of 500 cases of rheumatism in all ages studied in Bellevue Hospital a few years ago, 56 per cent. showed some form of chronic heart disease. After 30 years of age, another great cause of heart disease is syphilis, and syphilis injures the heart and arteries not in the late secondaries, as is generally believed, but often in the early secondaries. Such a syphilitic usually breaks down at about 45. After 50 years it is the degenerative process producing atheroma which causes most of the cardiac diseases. The form of heart disease which injures most is that chronic condition around the auriculoventricular valve, closing slowly but surely, forming mitral stenosis. Although this begins in the early years of life it usually cripples the patient between 33 and 38 years of age. What is the best thing to do with these people? Dr. Guile, who founded the cardiac clinic in Bellevue Hospital, taught his cardiac patients three things: to avoid alcohol, tobacco and stairs. It is not a question of the valves involved, but of the myocardium. Each man must learn to gage the ability of his heart to withstand certain exertions and to learn the limitations of his exertion. It is the duty of the clinician to find out when and under what conditions these morbid processes begin and what can be done for them during the living hours of the patient. In Bellevue Hospital the total number of rheumatics since 1914 has continually diminished and there has been practically an even diminution in the total admitted of all ages. Since 1914, also, the dental clinics have been struggling with the teeth and the children's clinics with tonsils. Since 1914, a diminution is shown of the ratio of cases admitted between 20 and 30 years of age compared with the total number of cases coming into the hospital. So that for these years both the total number and the ratio to total number have diminished; hence attention to both tonsils and teeth has helped. I found that 65 per cent. of rheumatics showed bad teeth and 35 per cent. showed bad tonsils. Bad teeth seemed more to blame than bad tonsils for all ages. The syphilitic cardiacs predominate over the septic types in the hospital today; previously the rheumatic cardiacs formed the majority. The prevention of sepsis, syphilis and arterial degeneration is what must be taught to improve public health in relation to heart disease.

DR. G. C. MCKINNEY, Lake Charles, La.: Dr. Conner mentioned that 1.6 per cent. of schoolchildren in New York City have heart lesions, and Dr. Lambert drew attention to the teeth and tonsils. I would like to call attention to the fact that Dr. Lambert said "bad tonsils" and not "hypertrophied

tonsils," because a tonsil may be very bad although not larger than a peanut. This expression "hypertrophied tonsils" should be dropped from the medical nomenclature. It means nothing whatever.

DR. WILLIAM H. MERCUR, Pittsburgh: The one special feature of Dr. Conner's work which always impressed me as most valuable and practical he did not especially emphasize. He devised and carried out a plan by means of which suitable occupations can be taught to hospital patients who are suffering from advanced cardiac lesions; patients whose compensation constantly breaks down whenever their former occupations are resumed. Those of us who are constantly seeing such patients must have observed with what regularity they return time and time again, either for hospital or private care, and always with greater frequency, until finally they can no longer work. A very large proportion of these patients, if taken early, and proper facilities given them, can be educated to earn their living in other ways, by carefully selecting more suitable occupations for them, in which their physical exertion is not out of proportion to their reserve cardiac strength. Such patients can thus have their life and usefulness prolonged for years and incidentally save our hospitals hours and hours of time. Few cities in this country have developed this idea to the extent New York has, and its success is chiefly due to the consistent efforts which Dr. Conner has made, not only to inaugurate this work but to see that his patients receive this necessary training. Those interested in carrying out this excellent idea in other cities would do well when they are in New York to look up the Sharon Work Shop, 84 Lexington Avenue, where this instruction is given.

DR. JOHN P. DAVIN, New York: We have a form of tenement house in New York that should be put out of commission, and that is the five story "walk-up." I am sorry that that tenement house was put up under the auspices of the Tenement House Commission. It was put up with the intention of doing away with the evils of the old tenement house. But there is nothing more conducive to heart disease in children who have tonsil trouble, than living on the fifth floor of a New York apartment building.

DR. B. A. LEDBETTER, New Orleans: One of the most important points to bring out in regard to this question of heart disease is the fact that the medical profession as a whole knows so little about it. Of all the organs in our body the heart is less understood than any other. I can look back on an experience of twenty-five years in examining a great number of people for insurance companies, and finding loud murmurs. Guided by my textbooks I felt sure that a person with such loud murmurs would be dead in a few years, yet some of those people are just as well now as they were then. The most serious heart diseases are unaccompanied by murmurs. On the other hand, a great number of murmurs are absolutely harmless. So long as the muscle is good the heart will work all right. It depends on the reserve that heart has, and it is by that that you must judge the case. At the necropsy, the valves in a great many of the cases are absolutely perfect. Do not think that because a man has a heart murmur you must lay him up. At the same time, however, we must not forget that with all these cases of heart disease, even mitral insufficiency, which is the least harmful of all heart diseases, the death rate is double that of the ordinary run of people. So that even in the mild cases you have to watch the patient. In those cases, we must find out what that heart can do. Then let the patient go ahead and do these things. He is going to die of something else. The same thing applies to schoolchildren. Many children come to us with heart murmurs. We cannot tell the damage done to that heart by listening to the murmur. Study the child. Do not stop that child from playing simply because it has a heart murmur. That child will stop himself if there is any serious damage to the heart.

DR. LEWIS A. CONNER, New York: I am entirely in sympathy with most of the sentiments of Dr. Ledbetter. We have to be very careful in protecting people with heart disease, but we have to be just as careful to protect healthy people from the stigma of heart disease. Quite as much

damage can be done in one direction as in the other, and success can come only from a better knowledge of the significance of heart murmurs. Only a very small percentage of them are really indicative of organic damage. I should like to emphasize the importance of the special heart dispensary classes in the management of heart patients who have had a breakdown and have been discharged from the hospital with their compensation more or less completely reestablished. It has been shown conclusively that such outpatient supervision can do much to prevent subsequent breakdowns and can save such patients from repeated visits to the hospital ward. But, while much can be done to save the already damaged heart from periods of decompensation, the great problem is that of the prevention of heart disease. There are three distinct types of damage: that due to rheumatic infection in early life, the syphilitic lesions of middle life and the degenerative types of trouble which are seen chiefly in the later years of life. The opportunities in this field of prevention are very great, indeed, if we can but get cooperation between the laboratory workers, the clinicians and the various public health organizations.

OUTLINE OF A SCHEME FOR WRITING THE NATURAL HISTORY OF SYPHILIS *

SANGER BROWN, M.D.

CHICAGO

Of the diseases that affect the human race, syphilis is certainly among the most formidable; and while within the last decade or two, owing to the brilliant development of laboratory craft, our conceptions of the malady have been materially extended and clarified, no corresponding progress has been demonstrated in the matter of prevention and cure.

About fifty years ago, before the natural history of pneumonia had been established, the scientific programs of medical society meetings, and the pages of medical journals presented a liberal display of papers extolling the specific virtues of various remedies in the treatment of that disease. When its natural history was understood, however, it immediately became obvious that nearly all the advocated measures of treatment had been more or less harmful and, indeed, in not a few instances had directly contributed to a fatal result. While the revelation of its natural history has not so far led to the discovery of a cure for pneumonia, it certainly cleared the field for action and has mitigated much suffering and saved many lives. If the natural history of syphilis were known, advantages might be expected similar to those referred to in regard to pneumonia.

In the treatment of any disease, the practitioner's ability to assess correctly the value of the remedies employed must depend on his knowledge of its natural history. It is recognition of the importance of this maxim that has prompted me to propose a plan for writing the natural history of syphilis; for so far this has not been satisfactorily accomplished, nor at the present time is there anywhere evidence of a movement in this direction.

Two outstanding obstacles bar the way when the task of ascertaining the natural history of syphilis is contemplated: One of these is created by the social and moral stigmas with which, according to popular verdict, syphilis stamps its victims. The other owes

* Read before the Section on Nervous and Mental Diseases at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

its existence to the protracted duration of the disease. Without my attempting either to state or to discuss the different views entertained at present regarding the course and curability of syphilis, probably all will agree that, in order to obtain the most accurate possible knowledge of the natural history of the disease, critical observations should cover the entire lifetime of a great number of patients, from birth when possible, but in any event beginning with the primary infection.

That the necessary histories can be secured and profitably studied only by an earnest and sustained coordinated effort of our profession may appear more obvious if some of the conditions incidental to the work are briefly stated.

NECESSITY FOR COOPERATION

In a considerable proportion of cases, a syphilitic patient, whether treated or not, regains his usual health within a period of two or three months of his primary infection, and even though during this period adequate clinical notes had been made, in many instances and for various reasons the physician is afforded no further opportunity of amplifying his record. Not until twenty years later perhaps, when symptoms of tabes or paresis appear, is the medical history resumed. Assuming that the clinical notations cover the remainder of the patient's life, including a necropsy, and that the professional services throughout were of the highest order, then so far as supplying a valuable contribution to the study of the natural history of syphilis is concerned, the commendable efforts of the several physicians connected with the case are largely wasted, because for a considerable period the patient would not have been under medical observation at all, and because it would rarely happen that the notes covering the period of initial infection would be available to the physician in charge during the final stages. Incomplete histories would be of only limited value for the purpose in view. In order to carry the proposed investigation to successful accomplishment many hundreds, perhaps thousands, of complete histories must be available for competent analysis. Manifestly these can be accumulated only by some sufficient scheme of cooperation.

For the purpose of enlisting and maintaining the interest and cooperation of the patient, appropriate propaganda should be prepared. This should appeal to his altruism; should convince him that his own interests would be best conserved by continuing for the remainder of his life under close medical supervision; should assure him that his acquiescence would in no way compromise his rights of professional privacy, and should make it clear that thenceforward without incurring any additional financial obligation he would receive the highest grade of medical service anywhere obtainable.

While many patients for various reasons would undoubtedly decline the terms submitted, it does not seem improbable that a sufficient number might accept and adhere to them to meet the requirements of the proposed investigation.

Conceding that it is important to obtain the specified histories; that a sufficient number of physicians might be induced to volunteer their services for the work incident to their production, and that the necessary cooperation of patients could be secured, practical plans for the successful prosecution of the project present themselves for consideration.

PROPOSED COMMITTEE AND ITS FUNCTIONS

The investigation of a subject like this one, which challenges the serious concern not only of the nation but also of the whole human race, and which for its successful prosecution requires the coordinated effort of a large number of well qualified physicians, should obviously be conducted under the auspices of the American Medical Association, our strongest, most representative and most authoritative medical organization. The appointment of a standing committee for this purpose would in my opinion constitute a legitimate expansion of the activities of the Association.

Assuming that a committee had been formed as suggested and was prepared to proceed with the work, meetings would have to be held to determine its scope, and methods to be adopted in carrying it forward. A campaign might be conducted to enlist the interest both of the laity and of the profession. Appropriate papers might be prepared and presented where they would be most effective. The services of both the lay and the medical press might be sought. The profession might be canvassed for volunteers who would be willing to contribute their services to the actual work of taking histories according to the prescribed methods. A manual setting forth the most approved and serviceable information on the subject of syphilis might be compiled for the instruction and guidance of workers.

In anticipation of flagging interest, the committee might see to it that close relations with the volunteers were maintained so that timely assistance and encouragement could be given. This would involve considerable correspondence and possibly quite numerous personal interviews, lectures and demonstrations. In the event of interruption of the relations between an observer and a patient, a method should be devised to secure continuation of the clinical record. Provisions would have to be made for analyzing, classifying and filing the histories, which would require both medical and clerical service.

The foregoing outline of the duties which would be required of the proposed committee demonstrates that, from the first, funds would be needed, and that it would be idle to attempt to carry the work to a successful issue without the assurance that ample funds were available.

CARRYING OUT OF THE PLAN

For the purpose of contributing to a more definite understanding of the proposed plan, let it be assumed that all desired conditions had been met. Then in some populous center, a constituent society of the American Medical Association, in which to initiate and develop methods for taking, collecting and filing the specified histories, should be selected. Those willing to participate actively in the work would have to organize; and from the first, to insure progress, the organization would require the services of a qualified paid executive. It is quite possible that the advisability might become apparent, as the work proceeded, of providing hospital accommodations for a limited number of patients presenting symptoms demanding special facilities for their satisfactory observation. As experience ripened, units might of course be multiplied as desired. Several units would naturally suggest the necessity of a central bureau from which all authority must emanate and to which a report of all activities must be submitted as the central committee might direct.

The scheme certainly sets a formidable task. It offers neither individual fame nor pecuniary reward; and while some beneficial results, especially from the

educational side, might be expected in the first decade, fifty years would probably be required for completion of the investigation, so that few if any of the earliest workers could hope to witness the full results to which their efforts had contributed. A strong spirit of altruism, high courage and energy are demanded for the initiation and prosecution of the subject. Hesitancy, criticism, and excuses are only natural under the circumstances; and yet, from the clinical side, unless we accept present methods of study and practice as final, a critical survey of the situation discloses no satisfactory alternative.

It may be stated here that a large standing army, providing its permanence could be secured, presents some exceptionally favorable conditions for study along the lines suggested. Some valuable results of work done in the Austrian army have already been published. But at best the range of military practice, under ordinary conditions, is not comprehensive enough to meet all the requirements of the proposed investigation; and furthermore, it does not include the highly important educational features to which reference has been made.

QUESTIONS THAT WOULD BE ANSWERED

In my opinion, from the clinical side the submitted scheme more than any other promises to shed needed light on such questions as:

1. What are the immediate and remote effects of various methods of treatment?
2. What proportion of syphilitics develop paresis or tabes?
3. Does any method of treatment influence liability to paresis or tabes?
4. In what proportion of cases does the Wassermann test remain positive in spite of all methods of treatment?
5. What are the various relations between cerebrospinal fluid and blood Wassermann findings? From a study of these can liability to paresis or tabes be predicated?
6. Can the wife of a syphilitic patient who is symptom free but has a positive Wassermann test acquire a positive Wassermann test from her husband without ever manifesting any symptoms of infection? And if so is she immune from further reinfection? And what is her liability to paresis and tabes? Similar questions would, of course, apply to the children of syphilitics.

This list of questions is intended to be merely illustrative; the investigation should undoubtedly cover the whole range of syphilitic pathology, and if the suggested committee be appointed, this should be duly recognized in its membership.

I respectfully submit that none of these or similar questions can be answered satisfactorily until the natural history of syphilis has been written.

PROPOSED RESOLUTIONS

I submit the following preambles and resolutions for your consideration:

WHEREAS, The deleterious effects of syphilis on the mortality and morbidity of the human race are so prevalent and so severe as to challenge the most serious attention of the entire medical profession; and,

WHEREAS, In the scientific study of any disease, knowledge of its natural history is an item of cardinal importance; and,

WHEREAS, Owing to the protracted course of syphilis, a continuous and complete clinical record of a given case can be secured only through the services of several successive medical observers; and,

WHEREAS, It is highly desirable that a sufficient number of completed histories be accumulated and preserved, and made easily accessible to students; and,

WHEREAS, For the successful accomplishment of the purpose set forth above, the interest and cooperation of a considerable number of the best elements of our profession as represented in the membership of the American Medical Association are necessary; therefore be it,

Resolved, (1) That the Section on Nervous and Mental Diseases of the American Medical Association recognizes the importance of ascertaining the natural history of syphilis and of making this history accessible and in form serviceable to students of medicine; further,

Resolved, (2) That the Section on Nervous and Mental Diseases of the American Medical Association respectfully requests the trustees of the American Medical Association to appoint a committee from the sections most immediately concerned, whose duty it shall be to devise practical means and methods of accomplishing the foregoing specified purpose; and further,

Resolved, (3) That the representatives of this section in the House of Delegates be requested to present these preambles and resolutions to the House of Delegates, and to ask its endorsement.

59 East Madison Street.

ABSTRACT OF DISCUSSION

DR. HUGH T. PATRICK, Chicago: No one could question the wisdom of this matter if it could be carried out. We all agree that it is something devoutly to be wished for. The difficulties lie in the details of carrying out the plan, but if they can be worked out by a committee so as to be made practical, as indicated by Dr. Brown, we have reason to believe that the necessary funds can be procured. Papers have been read to show that the incidence of tabes and paresis has no relation whatever to the previous treatment for syphilis; that tabes and paresis occur just as frequently in patients who have previously received good treatment for syphilis as in those who have not; and papers have been published to prove just the contrary.

DR. W. S. LINDSAY, Topeka, Kan.: Twenty years ago I treated a young man who had syphilis with the old-time salvarsan. About ten years ago several Wassermann tests were made, but the results were negative. He came to me for certification for marriage. On the basis of these negative reports, I signed his certificate. He has continued to have negative Wassermans, but the woman he married, whom I knew in childhood, as I had known him, had a still-born child and after that a positive Wassermann. She has had a second stillborn child and continues to have a positive Wassermann in spite of arsphenamin treatment.

DR. CHARLES D. HUMES, Indianapolis: I have been confused with the utter lack of knowledge regarding the date of infection, the amount of treatment that has been given, the nature of the after-care, if any, the character of the medical treatment, and the medical status of the patient immediately preceding the neurologic break. If those factors could be eliminated it would be a tremendous help to us and no doubt save many patients from the serious after-effects of syphilis. But until we can remove all the elements of human frailty and commercialism, it is very difficult to get patients to return to the office for so-called free consultation.

DR. C. R. WOODSON, St. Joseph, Mo.: I am heartily in favor of the resolutions that have been presented. The carrying and resisting capacity of men varies greatly, and it is hard to tell who will or who will not have paresis or tabes. I believe that paresis is less frequently found in those who have had thorough treatment than in those who have not had such treatment, but more particularly in those who have all "plus" habits, rather than in those who have excellent habits. A pathologist of some experience has expressed the belief that paresis was extremely rare, and perhaps never existed in those men who have never dissipated. I do not remember having observed this but if so it is in line with my belief of the effect of the "plus" habits.

DR. SANGER BROWN, Chicago: This paper was not intended to bring up any discussion on the course of syphilis but simply to outline a plan which might enable us to secure reliable data to work with when we wish to establish the value of any particular method of treatment that might be employed in the disease. Before the natural history of pneumonia was understood, a considerable part of the programs of medical meetings was taken up with papers extolling the specific virtues of certain remedies in the treatment of that disease. In the past few years the programs of medical meetings have shown a similar display in regard to syphilis. After the natural history of pneumonia was demonstrated and understood, the papers ceased, and it was understood that the extolled specific remedies had been, for the most part, meddlesome and harmful and in some cases directly contributory to a fatal result. It is quite possible that when the natural history of syphilis is understood, similar results may be noted.

RADIUM TREATMENT OF CANCER OF THE ESOPHAGUS UNDER ROENTGEN-RAY CONTROL *

R. WALTER MILLS, M.D.

AND

JOHN S. KIMBROUGH M.D.

ST. LOUIS

Cancer of the esophagus is one of the most distressing diseases. The inability to swallow adequate amounts of food and water, the regurgitation, strangling and sternal oppression, and the appallingly rapid loss of weight and strength characterize a disease that is truly terrible. To meet the appeals of the patient, who is abject in his willingness to undergo any sort of treatment, the physician has nothing to offer. The situation is uniquely hopeless from a radical standpoint, saving possibly the efforts of a few heroic surgeons whose specialized skill is usually not available or applicable. Palliative treatment is distressing and unsatisfactory. It is an added humiliation that cancer of the esophagus probably gives the earliest symptoms, is readily possible of at least as early diagnosis as any internal carcinoma, and that metastases occur late. It is obviously advisable to present any feature of a treatment that offers a prospect of relief, or with the greatest caution a possibility in its ultimate development of a cure of the disease. It is with this feeling that we report a few cases treated with radium under roentgen-ray control, emphasizing that the series is small and that the cases have been under observation at the longest only eighteen months.

There is as yet very little literature on the treatment of cancer of the esophagus by radium. The method seems to have been first used independently by Einhorn and Exner. Exner¹ reports three cases treated by the application of 60 mg. of radium, mounted on a bougie, to the region of the stricture for periods of twenty or thirty minutes on a number of successive or alternate days. In 1904, Einhorn² reported nine cases of esophageal cancer treated by radium. Later, seven

additional cases were reviewed.³ Special applicators of the bougie type were employed. Still later, Einhorn⁴ reviewed a series of seven cases of cancer of the stomach treated by radium, two of which involved the cardia and presumably the abdominal esophagus since they are referred to as esophageal lesions. A larger amount of radium, 70 mg., left in situ as long as six hours was employed. The matter of filtration is not emphasized. Results were palliatively beneficial. A formal report of a considerable series of cases is that of Janeway, Barringer and Failla⁵ from their work at the New York Memorial Hospital. These authors report twenty-two cases of cancer of the esophagus treated by radium. On account of their experience with the use of radium in other conditions, their report is comprehensive as to the demands and difficulties of the method applied to cancer of the esophagus. A. E.

Hayward Pinch⁶ reports one case of cancer of the esophagus treated by radium, and mentions another. Great improvement resulted in the case reviewed, gastrostomy being averted. Death from metastases occurred a year later without recurrence of dysphagia. The patient was "twice treated with a powerful emanation tube for fifteen hours." Chevalier Jackson⁷ goes at some length into the technic of radium therapy in cancer of the esophagus as to principles of filtration and especially the employment of esophagoscopy in the emplacement of the radium. He mentions Mr. Walter G. Howarth as obtaining excellent results through the employment of 100 mg. of radium left in situ for periods of eight hours on two or three occasions within a few days. Dr. C. W. Hanford⁸ has treated two cases of esophageal cancer with radium. One of the patients died from rupture of the

Compare with Figures 2, 3 and 4 of same patient with same treatment.

esophagus. The second patient was materially benefited, but was lost track of after the second treatment.

The highly beneficial and probably at times curative effects of radium in certain carcinomas, notably in cancer of the cervix uteri, is an established fact. Abbe⁹ reports a case of this disease in which

the patient is alive and well nine years after treatment.¹⁰ At first sight it would seem that radium should be equally effective in the treatment of cancer of the esophagus. The treatment of cancer of the esophagus, however, is a more difficult matter. The problem resolves itself into a question of the effective irradiation of the lesion without harm to contiguous normal tissue or stimulation of any portion of the growth, and is naturally connected with the matter of dosage and the mechanics of application.

The beneficial action of radium on malignant tissue is due to its selective retrogressive action on the cancer cell when used in a dosage still not harmful to normal tissue. When one is attempting to utilize this principle in the practical therapeutic use of radium, certain difficulties are encountered. First, what may be termed the coefficient of tolerance of normal as compared to pathologic tissue is not as great as would be ideal, and second, the devitalizing action of radium on malignant tissue rapidly decreases with its distance from such tissue. This decrease is approximately as the square of the distance. The thickness of a malignant tumor not being known, it follows that it is desirable to use as strong a dose as will be tolerated by surrounding normal tissue incidentally exposed to its action. In cancer of the uterus, conditions are maximally favorable, as it is possible on account of anatomic conditions to irradiate, in the center of a mass, the cancer-infiltrated uterus. Even if normal uterine tissue is injured, surrounding structures and reactions are such that protection is developed. The beneficial results of radium treatment in uterine carcinoma are due to the fact that under such conditions large dosage can be used. To cite another instance of effective radium therapeutics in which other conditions make possible other technical procedures, in superficial carcinoma, as of the lip, relatively large doses of radium can be utilized through centralization of application and protection of normal surrounding tissues by filters. The problem offered by carcinoma of the esophagus is quite different from that of other malignant conditions in which favorable results have been obtained. We have to do with a tumor whose exact thickness is unknown and usually not uniform. Not only is there no surrounding tissue of a protective nature, but instead, the thin-walled esophagus is in contact with vital structures whose devitalization may lead to ulceration and perforation. The situation of

cancer of the esophagus renders exact centralization of application and protective procedures mechanically difficult.

There is as yet no accepted criterion as to the amount of irradiation that the normal esophagus will tolerate. While this would at first thought suggest a safely minimum dose, it must be recalled that if benefit is to be derived the dose must be large enough to be definitely active throughout the entire tumor, because smaller doses, while favorably affecting immediately contiguous malignant tissue, may reach more distant portions of the growth so weakened as to be stimulating rather than inhibiting. If there is to be a prospect of a cure of the disease, it would seem dependent on a considerable dose being employed. The situation as regards cancer of the esophagus is not one that indicates temporizing. The disease, saving possibly a rare

surgical cure, is fatal, and its course is attended by suffering and a distressing lessening of morale. If in any condition a treatment embodying an element of risk is justifiable, it is so in this instance. It would seem that the maximum dose compatible with a fair degree of safety must be conceded as the primary requisite. The problem secondarily is one of precise application and protection. Regarding the first difficulty, it is hoped that this presentation may offer aid; of the second, it less definitely suggests possible help.

Requisites to the successful emplacement and continuous application of radium in cancer of the esophagus are: (1) a knowledge of the location and physical peculiarities of the tumor and the resulting stricture, especially as to location, extent, direction, and the degree of stenosis; (2) a

means of effective and nontraumatizing canalization of the cancerous stricture; (3) a mechanical means of maintaining the radium in direct application with the tumor; (4) a ready means of frequent observation as to the position of the radium during the period of treatment, and (5) a careful selection as to dose, filtration, and frequency of treatment guided by such experience as we have and the individual peculiarities of the case.

Esophagoscopy has heretofore been utilized by some to accomplish certain of these ends. Esophagoscopy plus careful measurement will ascertain the location of the proximal portion of the tumor. Sounding by olive tip bougies or gastrostomy will serve to locate its probable distal boundary and give a general idea of the luminal inequalities of the stricture and determine its degree. Esophagoscopy can through recovery of

Fig. 2.—The radium-bearing capsule is shown just canalizing the upper reaches of the cancerous stricture.

10. The patient still remained well in October, 1919, ten years after the initial treatment (personal communication to the authors).

tissue establish the diagnosis, though not admirably according to present surgical teaching. Esophagoscopy might serve to map out the topography of the stricture in certain unusual instances in which it was not so great but that it could be canalized by the esophagoscope. It will also serve as a means of emplacing radium, at least within the upper reaches of the cancerous stricture. Esophagoscopy can best determine tissue reaction after a radium treatment. The procedure has as its disadvantages those natural to such an instrumentation. In most instances it cannot give a definite knowledge of tumor topography but only of the proximal end of the stricture. It furnishes no means of ascertaining the permanence of location of the radium after it is initially placed without frequent instrumentation, and then no clue as to its location and relation to the tumor when it is necessary to place it below the initial stricture, as is frequently the case.

The roentgen ray has advantages over esophagoscopy for certain of the purposes in question, and may be successfully utilized to serve ends impossible by it, especially in that it furnishes means of frequent and convenient observation as to the location of the radium in any level of the stricture during the entire treatment. The foregoing is a very important matter, as it has been found that the radium terminal almost invariably sooner or later slips into lower portions of the stricture or beyond it, less frequently above into the dilated esophagus. Again, the use of fluoroscopy during the emplacement of the radium capsule is an effective means of aiding in the canalization of the cancerous stricture visualized by the patient's having just previously swallowed a small amount of bismuth in suspension.¹¹ It is frequently an advantage to bend the

wire carrier slightly at its attachment to the radium capsule so that the terminal is deflected at a slight angle. Torsion on the oral end of the wire applicator, and the placing of the patient at different angles will make it possible to guide the terminal directly into the stricture. In certain cases of marked cancerous stenosis, the tip of the radium terminal may be made to engage within the proximal portion of the stricture; but further progress is prevented by the degree of narrowing. In such instance, under careful fluoroscopic control the tip may be left engaged in the stricture, the walls of the esophagus above being protected by the distention of the esophagus proximal to the

stricture by a bismuth mixture. It will usually be found on later observations that, owing to the continuous gentle pressure exerted by the spring of the wire applicator, the radium gradually canalizes the lower levels of the stricture. In case the stricture is not visualized at any time, it may be made apparent by the simple expedient of having the patient swallow a teaspoonful or two of bismuth medium alongside the wire applicator.

It is difficult to understand how any approximation of the radium to the body of the tumor can be effected by other than some sort of visually controlled method; a matter that is fundamental and the importance of which is becoming more and more recognized. In many cases the strictured lumen is devious, and opens from the proximally dilated esophagus to one side. It is remarkable what aid can be obtained by fluoros-

copy. A threatened false passage is strikingly indicated. The cause of failure to canalize any portion of the stricture is shown to be usually due to impingement of the terminal against the wall of the stricture on account of an abrupt curve rather than to a local narrowing. Plates taken and developed between efforts at introduction and as a record of emplacement at any given time are helpful.

While less appealing, the roentgen-ray diagnosis of cancer of the esophagus in expert hands, taken in conjunction with the clinical history, will probably attain as high a percentage of accuracies as can be realized by esophagoscopy. Occasionally the roentgen ray serves to visualize the actual shadow of the esophageal tumor silhouetted between those of the heart and the spine. If a technic can be evolved that will do this with any constancy and especially in other than the diagonal poses, it will be of great

advantage, as the actual extent and various thicknesses of the mass can be determined and the radium not only more effectively placed but a basis established for control of tissue-protective unilateral filtration, this with the view of using larger dosage when conditions make it desirable. Most hopeful in this regard is a technic developed along the same lines as in gallbladder work, namely, strong fixation of the patient, the use of small diaphragms, extreme care as to the suspension of respiration, and a careful technic of exposure adapted to the individual patient. Fast screens are best used to obtain speed in exposure necessitated on account of transmitted movement from the heart's impulse. The roentgen ray also serves as a means of determining the results of treatment, so far as the degree of stric-

Fig. 3.—The radium capsule is shown as left in situ during the first half of the six-hour treatment. Note that the normal esophagus above the cancerous stricture is protected by the distention of the dilated esophagus. The capsule is left in this position for three hours, and then further introduced to treat the lower half of the lesion, as shown in Figure 4, for the remaining three hours.

11. Bismuth in small amounts gives a slightly heavier shadow than does barium.

ture and to some extent of the change in the tumor is concerned. The roentgen-ray control of irradiation of cancer of the esophagus has all the unique advantages and gives the peculiar satisfaction and surety that is characteristic of the use of the roentgen ray elsewhere. As an aside, the roentgen-ray method of control may be used in other esophageal instrumentations, such as the divulsion of strictures with opaque bougies and as one of us (Mills) has used it for some two years in the treatment of cardiospasm with a special bismuth-containing lead-mounted dilator. The dilatation of cardiospasm under roentgenoscopic control is a revelation.¹² In comparing esophagoscopy and the roentgen ray for the control of the treatment under discussion, it is not implied that either alone should be relied on if advantages possessed by either method are unique for certain purposes. Both should be used according to the indications.

SUMMARY OF TECHNIC

An initial roentgen-ray study of the position and physical peculiarities of the tumor is made by both screen and plate, a simple mixture of bismuth subcarbonate in water being used as a means of visualization, and, when the stricture is not great, bismuth suspended in artificial buttermilk. If plates are taken an instant¹³ after the patient is told to swallow a mouthful of the barium-containing substance previously held in the mouth while in pose, the stricture and distal esophagus will usually be visualized. If the stricture is of high grade, the act of swallowing tends to force through it bismuth previously swallowed and retained above the stricture. When the stricture is less marked, the fact that the contrast substance does not pass through the cardia as rapidly as usual, possibly through inhibition in the conductivity of the nervous impulses governing peristalsis, is a help in visualizing the lower esophagus.

The patient is given a preliminary injection of morphin and atropin one-half hour before the radium

treatment is begun, the dose obviously as indicated. It is impossible to overestimate the value of this procedure in quieting the patient and making the endurance of a six-hour application possible without undue suffering. Many patients sleep through most of the treatment. Occasionally, in marked strictures, a spoonful of olive oil one-half hour before treatment is helpful in relaxing secondary spasm. Preliminary bouginage is occasionally useful. The radium enclosed in a container composed of German silver 0.5 mm. in thickness and further filtered with 0.5 mm. of brass and a thickness of rubber is mounted as a terminal on a slightly springy drawn silver wire encased in a rubber tube. It is introduced after the manner of an ordinary esophageal sound. A wire applicator has been used by others. In certain cases in which the abdominal esophagus was involved, the radium with its filters

was encased in the end of a rather small stomach tube, as it was sometimes found that the wire carrier could not readily and safely take the rather abrupt curve of this portion of the esophagus. The wire applicator or stomach tube bearer is anchored by means of a bridle bandage about the patient's head (Fig. 5). The radium is left in situ for six hours at each initial treatment. Cases were treated on from one to seven occasions. The frequency and number of treatments and the length of other than the initial treatment was occasionally varied somewhat to meet individual indications; also as much as thought advisable in an effort to determine the most effective procedure. Nearly all our work has been done with 50 mg. of radium element. It is probable that the use of radium emanation not available to us would have advantages over the element on account of the more advantageous form

Fig. 4.—The radium capsule is here shown in the lower half of the cancerous stricture, where it is left in place during the second three hours of the treatment. Were esophagoscopy alone used, such an emplacement would be impossible of observation.

of applicator that it would permit. Our greatest difficulty has been due to the thickness, length and rigidity of the radium-containing receptacle with its filters, which precluded satisfactory introduction in certain marked and irregular strictures.

The immediate results of the treatment were in most instances beneficial, sometimes strikingly so as to the relief of the dysphagia. No case treated failed of improvement in this regard. The improvement in several was almost immediate, within twenty-four hours, possibly owing in part to a bouginage action of the radium capsule. A gain in weight occurred in most cases. Curiously, the results of treatment are not reflected by a reduction in the local esophageal deformity and stenosis commensurable with the functional improvement—possibly owing to loss of local distensi-

12. Fluoroscopic control of cardiospasm dilatation shows that it is difficult to cause the dilator to straddle the site of spasm, and still more difficult to cause it to remain in place during the divulsion. It also shows that the best way to accomplish this is to introduce the dilator beyond the hiatus oesophagi, to distend it very slightly, and then pull it into the area of the stricture and, while holding it in place with considerable traction, inflate still more. The roentgen ray also strikingly shows that the standard dilator is much greater in diameter than is necessary. The spastic area is never dilated to anything like the full diameter of the dilator at the time pain is elicited. Judging by those divulsions that have been done under fluoroscopic observation, it is difficult to understand how full dilatation of the spastic area could be accomplished without danger of rupture of the esophagus. When full dilatation is accomplished, the dilator is probably either above or below the seat of spasm. The moderate distention referred to above is entirely adequate to accomplish the most beneficial results.

13. This time varies somewhat according to conditions in the individual case, but is usually about three seconds.

bility. In several cases there was a return in a degree of the dysphagia, usually relieved by another treatment. The reestablished dysphagia in some instances seemed of the nature of intermittent spasm. The late return

Fig. 5.—Method of fixation of the radium carrier by means of a bridle bandage.

of the dysphagia may be due in some cases to secondary contractures. It may be mentioned that radium burns result in dense scar. Perhaps, with added knowledge, late careful dilatation by bougies might be beneficial; we have not attempted it.

The propriety of reporting and reviewing a small series of cases under observation only a short time may justly be questioned. On the other hand, we feel that this is advisable under the circumstances. If workers delay reporting cases until several years have passed and final conclusion as to the value of the method is reached, valuable time will, indeed, be lost. We can at least profit by one another's disasters, which are usually prompt. The matter of dosage, too, can be helpfully influenced if cases showing immediate beneficial results are reported. Again, carcinoma of the esophagus is relatively rare. If we delay until any considerable series of radium-treated cases is accumulated, the development of the method will be prolonged. A presentation of cases, even with definite limitations, will help develop an interest in the method and serve as an incentive to earlier diagnosis which is, after all, the prime requisite on which our hopes are built.

Our own tentative results may be thus summarized: Eleven cases were treated. No case was treated which might be considered a cure, though one patient is alive and in good shape eighteen months after the first treatment without evidence of metastasis. The esophagoscope shows no appearance suggesting present carcinoma. Others have been under observation less than a year. No case treated could be considered early, and most of them were frankly advanced. There was but one case in which there was evidence of metastases, and in that instance there was involvement of the stomach as well as the abdominal esophagus. Five patients have died, one possibly of perforation

resulting from the treatment. In six cases the dysphagia has been strikingly improved. In four additional cases the improvement in swallowing has been definite, though intermittent. Seven cases were improved as to general condition. In certain of these generally improved cases the result was so striking as to indicate that the treatment is strongly advisable even when there is no possibility of a cure. There seems no question but that life is prolonged by the treatment. The patients are usually enabled to continue their work. Not the least of the benefits is the improvement in morale. The work, instead of being gruesome, is made gratifying by the pitiful appreciation of the patients.

A mention of the results of others in the treatment of cancer of the esophagus by radium is fitting, though these instances are few. In Exner's cases, favorable results were considered indicated by decrease in the degree of stenosis as determined by bouginage. In Einhorn's series, the majority of cases were palliatively improved, and decrease in the local lesion was considered indicated in certain instances by increased distance of the stricture from the incisors. Janeway, Barringer and Failla may be thus quoted: "The series of cases reported by no means justifies a gloomy outlook. Cases too late for a cure by radium can receive palliative relief." But one patient was sufficiently benefited to encourage belief in complete retrogression (this case had been under observation a little more than a year). Five cases were definitely improved. One patient who

improved had an advanced lesion at the time treatment was begun. Fifteen patients were not improved; the authors felt on account of the advanced state of the lesion and the too frequent treatments. Pinch reports a case of epithelioma of the esophagus treated by radium. The patient lived one year, dying from metastases. As far as the local condition was concerned, the treatment was eminently satisfactory: "infinitely better than could have been obtained by gastrostomy." Chevalier Jackson

mentions having treated cases of cancer of the esophagus by radium and states that he has seen marked favorable effects in inoperable cases, but so far no cures. He prefers to wait several years before passing judgment. He speaks of the help-

Fig. 6.—Distention of the normal esophagus during the swallowing of one large mouthful of contrast substance. The plate is taken during an act of deglutition with a very short exposure. Note how any small defect must be evident if present.

fulness of surgery in the condition, and of having seen no case amenable to operative treatment in which he would consider the use of radium justified. He mentions Mr. Walter G. Howarth as obtaining excellent results by the method. Hanford obtained material benefit in one of the two cases treated by him.

The question of the treatment of cancer of the esophagus by radium versus surgical treatment should be mentioned. If the lesion is definitely early and favorably situated and the rare surgical experience available, surgery may be the method of choice. Actually, such a combination will rarely occur. Possibly as the importance of early diagnosis becomes more appreciated and the surgery of the lesion is developed, operative treatment will be more frequent.

As to palliative treatment, the indications are that radium therapy is the best that has yet been suggested; at least, patients may live to die of less agonizing

not only in the treatment of cancer of the esophagus by radium, but also in other esophageal instrumentalities.

REPORT OF CASES

CASE 2.—Mr. L. C. B., alive eighteen months after the first treatment, was in fairly good condition when first seen; he was 20 pounds underweight. The case was moderately advanced; he had been sick six months. The lesion was moderately limited, affecting the lower esophagus, with moderate stenosis. Marked improvement followed the treatments, especially the third at five months. The weight increased from 121 pounds to 130 pounds in thirteen months, yet there was only moderate improvement in the dysphagia. The fourteenth, fifteenth and sixteenth months were bad on account of intermittent dysphagia, symptomatically suggestive of cardiospasm, though the roentgen-ray findings were against such. During the sixteenth month, there was a sudden improvement in swallowing, there being practically no difficulty. The patient takes a general diet, including such articles as turkey, cranberries, sardines, and pork tenderloin. Roentgen ray reveals definite improvement in esophageal canalization, though still a narrow area. Esophagoscopy reveals local narrowing with semilunar-like horizontal bands only in the strictured area. The patient is holding his weight at 113 pounds and is working as a porter. Four radium treatments were given, two the first five days, the third after five months, and the fourth in the fifteenth month. The treatments were well tolerated. This case may be classified as highly successful, with palliative if not curative result. The lesion is demonstrably improved, as visualized by roentgen ray. The dysphagia has greatly improved. The result has been so good as to make diagnosis questionable, though there was no other

Fig. 7.—How the esophagus distal to a quite marked stricture is filled during the act of swallowing. The defect in this instance is that of a fairly early carcinoma. Note how sharply its limitations are shown. The shadow of the tumor itself is also apparent.

consequences than result from esophageal stenosis. From a consideration of all factors, the possibility of the ultimate cure of certain cases of cancer of the esophagus by radium must be held a possibility.

The method just described would undoubtedly be more effective if patients could be secured in an early stage of the disease, rather than, as in our cases, when the condition was advanced and even desperate. It is sad that it must almost seem a part of the classical anamnesis of cancer of the esophagus and stomach to have the patient relate that he was at first seen by one or more physicians who gave him medicine without an examination. Cancer of the esophagus can be diagnosed in a few seconds by the roentgen ray. It seems amenable to radium therapy in the same way as does cancer of the mouth, which it histologically resembles. If the cooperation of the profession can be secured and the importance of early diagnosis realized by them, it will be a great advantage.

CONCLUSIONS

The method of treating cancer of the esophagus by radium is hopeful. The most encouraging feature in the small series of cases treated is the relief of the dysphagia. The roentgen ray gives valuable help through establishing a knowledge of the peculiarities of the individual lesion, as an aid in the emplacement of the radium and in the control of its localization. Its use suggests other possibilities as to its employment,

Fig. 8.—Shadow of the cancer itself asymmetrically surrounding the defective portion of the esophagus and probably extending below on its anterior wall.

reason to suspect other than carcinoma. The Wassermann test was three times negative. There was no previous history of dysphagia or esophageal traumatism.

CASE 3.—Mr. P. M. died suddenly four months after the first treatment and four weeks after the last treatment,

apparently in profound shock; he was cyanotic, etc.; the trouble began with a chill; he was able to take nourishment. Otherwise, there was nothing to suggest perforation; he had definitely improved, and was at work. When first seen he was in fair shape, but was 20 pounds underweight. There was a moderately early lesion at the juncture of the second and lower thirds of the esophagus, with moderately marked stenosis. Four radium treatments were given, with only slight temporary improvement in the dysphagia, yet the patient's general condition definitely improved. At the end of six weeks, his condition was worse. His weight diminished from 124½ pounds to 112 pounds. Bougie dilatation was necessary before the emplacement of radium. Three additional radium treatments were followed by marked improvement in dysphagia, with the patient regaining weight to 125 pounds and apparently in good shape. He worked as a laborer to the end. The treatments were well tolerated. This case may be classified as having a moderately successful palliative result, the symptomatic improvement being greater than roentgen-ray findings indicated. This patient's death was possibly due to perforation.

CASE 7.—Mr. C. H. is now alive, six months after the first treatment. His general condition when first seen was fairly good. It was a moderately advanced case. He had been sick four weeks, and was 25 pounds underweight. There was a fairly extensive lesion at the juncture of the upper and middle thirds of the esophagus. There was a moderately marked stenosis. The patient's general condition immediately improved markedly. He gained 10 pounds during the first month. There was a marked improvement in dysphagia for two months. During the third month there was a slight recurrence of dysphagia, though he was able to eat rice, carrots and cabbage. He lost 4 pounds in the third month, though he still weighed 6 pounds more than when first treated. The weight loss was possibly due to inability to obtain suitable diet. He was not working regularly, but was able to do light work. Two radium treatments over a period of three days were given, the first irradiating the upper half of the stricture, the second the lower half; a third radium treatment at three months and a fourth at five months after the initial treatments were given. At present there is rather more dysphagia than after the initial treatment, probably because it has never been possible to canalize the lower zones of the stricture on account of an unusual curve. At present he is able to eat a semisolid diet, oat meal, milk toast, rice, etc. The treatments were well tolerated. The patient's general condition is fairly good. This case may be classified as having a definitely successful palliative result. Roentgenoscopy indicates improvement in the lesion, especially as to canalizability, though there is still definite evidence of stricture.

CASE 8.—Mr. L. J. C., who is still alive, six months after the first treatment, was in fair condition when first seen. There was quite a limited lesion involving the abdominal esophagus. Probably this was a fairly early case, the patient being sick only two months, with a 40 pound weight loss. There was only slight stenosis. There was a marked improvement in his general condition. He gained 12 pounds in the first three months. There is absolutely no dysphagia at present. He is working steadily, though he was not able to before receiving treatment. Two treatments were given, the

second at three months. The radium was encased in the terminal end of a stomach tube (on account of the curve of the abdominal esophagus). There was no difficulty in retention in situ. The treatments were well tolerated. The general result may be classified as good. There is practically entire relief of dysphagia. The condition suggests a possibility of ultimate cure. The roentgen ray reveals structural improvement in the lesion and good canalization of the involved esophagus. It is a question as to whether he should not have been more vigorously treated initially or subsequently.

Wall Building.

TUMORS OF THE RENAL PELVIS

WILLIAM E. STEVENS, M.D.

SAN FRANCISCO

Papillomas, although not uncommon in the bladder, are seldom found in the pelvis of the kidney, and comparatively few cases have been reported in the literature. The case that I present is unique in that the tumor of the pelvis was apparently secondary to the

bladder growth; at any rate, no symptoms of renal involvement occurred for more than one and a half years after the appearance and destruction of the bladder papilloma. I have not been able to find a similar case recorded in the literature. Occurring primarily in the pelvis of the kidney, the grafts are supposed to be carried by the urine to the lower portion of the urinary tract, such as the ureter and bladder. In my case the late involve-

ment of the pelvis is more difficult of explanation. Possibly extension occurred through the lymphatics. Of interest also is the fact that in cases previously reported this condition has been found only in patients under 60 years of age, and it has usually been multiple.

REPORT OF CASE

M. S., a man, aged 70, unmarried, bartender, had suffered from slight pain in the right lumbar region during the last year. He had noticed blood in the urine for the last twenty-four hours. His father died of "prostate gland trouble" at 70, his mother of diabetes at 73, a brother of pulmonary tuberculosis at 40, and his other brother of "rheumatism," at 56. He had measles when a child, gonorrhea in 1871 and in 1904, a genital sore in 1907, and dysentery in 1899. In 1913 he noticed blood in the urine, and was troubled with frequent urination. Cystoscopy at this time revealed a pedunculated papilloma to the left of the left ureteral orifice. The symptoms disappeared following removal of the tumor with snare and cauterization. Nineteen months later, January, 1915, he was in the hospital for two weeks because of severe pain in the right kidney region. His urine contained a trace of albumin, many hyaline, granular and cellular casts and some pus, but no blood cells at the time. Catheterization of the ureters revealed a few pus cells in the urine of the right kidney. The symp-

Papillary epithelioma of the renal pelvis.

toms disappeared following rest in bed. Three years later, April, 1918, he entered the hospital because of blood in the urine. Examination of the urine at this time disclosed many blood cells, a trace of albumin and a few pus cells, but no casts. Cystoscopy revealed an inflamed bladder mucosa and somewhat bloody fluid escaping from the right ureteral orifice. Comparative functional kidney tests were negative. The urine was free from blood at the end of a week, and the patient left the hospital. Six months later he reentered, stating that he had suffered from slight pain in the right lumbar region for the last year and that he had noticed blood in the urine for the last twenty-four hours. Cystoscopy again revealed bloody fluid escaping from the right ureteral orifice. The bladder mucosa was normal. Functional kidney tests gave diminished values on the right side. The wax-tipped catheter showed no evidence of calculi. Pyelography demonstrated a right kidney pelvis somewhat elongated laterally and the ureter entering the pelvis at a right angle. A diagnosis of tumor of the kidney was made, and operation was advised and accepted. A large papilloma the size of a walnut was found when the pelvis was opened. No evidence of ureteral involvement was present.

COMMENT

As in vesical growths, two types of papilloma of the renal pelvis are recognized, the benign, which is usually pedunculated, and the malignant, which is usually sessile. The former has the characteristic tendency to assume the latter type.

Etiology.—Several theories have been advanced to explain the etiology of these tumors. The fact that stone has occurred as a complication in 15 per cent. of the cases reported has led to the belief that the traumatism associated with this condition is often responsible for the epithelial proliferation. Morogna, quoted by Judd, believes that they are due to aberrant ectodermal inclusions during the period of development, the growth of which has been excited by some inflammatory process.

Symptoms.—Unless because of the position or size of the tumor obstruction is present, the symptoms most commonly noted are hematuria, intermittent in character, and some frequency of urination. In the presence of obstruction, pain is a prominent symptom.

Diagnosis.—If a history of vesical papilloma is present, pelvic tumors should be easier of diagnosis in the early stage than tumors of the parenchyma. Cystoscopy often reveals blood ejected from the corresponding ureteral orifice, and pyelography will disclose a deformity of the renal pelvis. If obstruction exists in addition to pain, hematuria will often be found, and a diminution in the size of the kidney following the emptying of the pelvis will be observed.

Differential Diagnosis.—Roentgenography and the wax-tipped catheter are of value in excluding calculi. The absence of tubercle bacilli and pus cells from the urine, together with a negative roentgenogram, exclude tuberculosis, and the pyelogram demonstrates a normal pelvic outline in the renal varix, so-called essential hematuria and nephritis. The intermittent character of the bleeding serves to differentiate pelvic tumors from those of the parenchyma of the kidney, as in the latter, bleeding is usually continuous. The history of bladder and especially ureteral papilloma justifies a strong suspicion of pelvic involvement.

Treatment.—Because of the frequency of recurrences and the tendency of the benign type toward malignancy, nephrectomy is indicated in every case of papilloma of the pelvis of the kidney. As the ureters are involved in the majority of cases, ureterectomy is also advisable.

Shreve Building.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

W. A. PUCKNER, SECRETARY.

CELLUFLOUR.—Cellulose Flour—D. C. L.—Commercially pure cellulose in the form of flour.

Actions and Uses.—CellufLOUR is used as a means of filling out reduced diets as in the Allen treatment for diabetics. It is a nonnutritive food substitute used to give bulk to foods, thus serving to satisfy hunger without furnishing nourishment.

Dosage.—CellufLOUR, after admixture with bran, baking powder, eggs, "India gum," or liquid petrolatum in varying proportions may be used for the preparation of imitation bread, muffins, cookies, griddle cakes, pie-crust, etc. These preparations may be seasoned with salt, spices or saccharin.

Manufactured by the Dietetic Cellulose Laboratory, Chicago. No U. S. patent. U. S. trademark applied for.

Purified and bleached wood pulp, straw pulp or cotton fibre is further treated to facilitate grinding to flour.

CellufLOUR is white to grayish white in color; odorless and tasteless.

DIAPROTEIN PREPARED CASEIN FLOUR.—Casein to which has been added 4 per cent. of a leavening mixture composed of sodium bicarbonate, monocalcium phosphate and sodium aluminum sulphate.

Actions and Uses.—This flour is employed in cases such as diabetes, etc., in which carbohydrates are contraindicated.

Dosage.—Diaprotein prepared Casein Flour is said to be adapted for the preparation of bread, cake, muffins, biscuits, etc.

Manufactured by the Diaprotein Company, Chicago. No U. S. patent. U. S. trademark applied for.

BENZOCAINE (See New and Nonofficial Remedies, 1920, p. 33).

Anesthesin-Abbott.—A brand of benzocaine complying with the N. N. R. standards.

Manufactured by the Abbott Laboratories, Chicago. No U. S. patent or trademark.

Instruction in the History of Medicine at Medical Schools.

—Haberlin (*Deutsch. med. Wchnschr.*, Dec. 18, 1919) recommends that courses in the history of medicine be established in all medical schools and that students should be required to take at least one full semester course. No one can be an investigator in the true sense of the word in the field of any science who does not inform himself as to what has been accomplished in his field of study before his own advent on the scene. In our own times, those empirics who trust to luck and have no regular plan of investigation that they follow are all too well known. Only through a knowledge of history can we form a certain judgment in regard to the many doctrines and therapeutic methods that spring up only to disappear again soon. As Vetter emphasized: "History alone encourages us to enter on a doubtful experiment, comforts us if we fail, warns us of the results of error, which so often, committed by a single person, is expiated and cursed by millions of people. The history of error is, then, the teacher of truth trained in the school of misfortune." The history of medicine, as of any science, brings before our eyes the struggles and strivings of thousands and thousands of human beings who have sought to discover the laws of almighty Nature and to use their thus acquired knowledge for the welfare and blessing of suffering humanity. It leads the student away from the realistic employments of the medical profession as found at the bedside of patients, in the laboratory and at the dissecting table; lifts his mind to that which is ideal and humanitarian, and fills his heart with noble enthusiasm for the dignity of his calling and the welfare of humanity.

THE CHEMOTHERAPY OF CHAULMOOGRA . OIL

Although many innovations have been attempted in the empiric treatment of leprosy, the use of chaulmoogra oil seems to have survived that of almost all the other "herbaceous remedies." This product is at present extensively employed and seems to produce amelioration in the majority of lepers to whom it has been administered persistently. With this record of therapeutic promise it was natural to expect a greater refinement of the crude oil which would perhaps result in isolation of the "active principle," or at any rate furnish a product more easily administered for remedial purposes by other than oral channels. Various fatty acids or mixtures have been separated from chaulmoogra oil within the last thirty years and administered by mouth to lepers, with indifferent success. In 1916 and subsequently, Sir Leonard Rogers¹ in India first attempted the therapeutic use of some of the fatty acids of chaulmoogra oil in subcutaneous and intravenous medication, employing them in the form of their sodium salts as soluble soaps.

Last year, considerable interest was awakened by the significant contribution of Holman and Dean² on this subject. They fractionated chaulmoogra oil by saponification; but instead of employing the undesirable soaps, they prepared the liquid ethyl esters of the fatty acids obtained from the oil. These esters are superior for subcutaneous administration. They have caused reactions in leprosy lesions with subsequent improvement; and several of the patients treated with the new products have become bacteriologically negative so that they could be paroled from segregation. Here, then, is the promise of progress, despite the fact that many new remedies have been hailed vociferously for the treatment of leprosy, only to be relegated after a brief trial to the list of forgotten medicaments.

What is the scientific explanation for the efficacy of chaulmoogra oil and its derivatives? Is the now demonstrated therapeutic action direct and bactericidal to the micro-organisms of leprosy, like that of arsphenamin on the spirochetes of syphilis, or does it act in some indirect and physiologic way to promote immunity? To these questions Walker and Sweeney³ have addressed themselves. Their investigations have demonstrated that chaulmoogra oil contains bactericidal substances that are about one hundred times more active than is phenol. The antiseptic potencies are attributable to the fatty acids of the chaulmoogric series, chaulmoogric and hydnocarpic acids, and possibly lower isomers of the series. The bactericidal action is specific for the acid-fast group of bacteria, to which the causative organism of leprosy belongs, the products being inactive against all other micro-organisms studied. It may be urged against the probability of the bactericidal property of chaulmoogra derivatives, as an explanation of therapeutic results, that their limits of potency in vitro are far below those of the therapeutic intravenous dosage in leprosy in which the drug may be calculated to exist in a dilution of 1:500,000 or greater of body weight instead of 1:100,000 found necessary in the laboratory. However, so long as the precise behavior of the fatty acids in the body is not known and the possibility of their concentration in the environment of the parasites cannot be denied, the factor of dosage need not offer a stumbling block to the hypothesis of chemotherapy offered. The drug may be stored in the tissues and thus ultimately reach a concentration essential for bactericidal action. This may explain the long time required for effective therapeutics. Or, again, the chaulmoogra products, even when present in suboptimal concentration, may inhibit or damage the lepra bacillus to a degree that renders it subject to the natural immunity responses of the host. For the present it does not seem necessary to invoke the hypothesis of special physiologic responses provoked by the introduction of the drugs.

Tuberculosis also involves the presence of acid-fast bacteria in its lesions. Hence it has been proposed to attempt for this disease a therapy similar to that of leprosy. The bactericidal action of the chaulmoogric acids against all members of the acid-fast group of bacilli, together with the clinical results obtained from their use in leprosy, as Walker and Sweeney point out, have furnished theoretical grounds for the application of the same products to the therapy of tuberculosis. The California bacteriologists have ascertained³ that the fatty acids of cod liver oil, the salts of which constitute the so-called "sodium morrhuate," do not possess the special bactericidal activity

of the corresponding chaulmoogric compounds, and hence cannot lay claim to a similar advantage which has been ascribed to them in the therapy of tuberculosis. The actual chemotherapeutic value of the chaulmoogric acid compounds in the treatment of infections due to the acid-fast group of bacilli, notably tuberculosis, remains to be proved by experiments on animals and then by clinical trial. It seems wise, however, to repeat the warning of Walker and Sweeney that the clinical tests of chaulmoogrates in tuberculosis should await the experimental investigations now in progress; for, as they remind us, the indiscriminate use of such drugs may arouse false hopes and be not without danger to the patients.

MORTALITY CLASSIFIED FROM A NEW STANDPOINT

One of the important advantages of well classified statistics of human mortality lies in the help they may afford toward the formulation of correct hygienic precepts. For example, a large amount of data collected in this country has been interpreted to signify that "the increase in the death rate with advancing years is not in accordance with a natural law, but the result of various factors susceptible of important modification." It is, indeed, highly imperative to establish such a contention on an incontrovertible basis. Thus, if we admit that many chronic diseases which figure prominently in middle life as causes of death are due to environmental factors, to improper living, mental and physical strain, dietary errors, and infections, a campaign of correction is eminently justified. If, on the other hand, hereditary and racial factors, the migrations of races and other essentially uncontrollable influences enter into the problem, it may be far less promising to attempt to avert conditions that are inherent and inavertible rather than acquired and remediable.

Raymond Pearl,¹ of the Department of Biometry and Vital Statistics at the Johns Hopkins University, has recently made an attempt to estimate the importance of some of the biologic factors that enter into mortality. Instead of classifying deaths according to special pathologic causations, such as bacterial infections, metabolic upsets and mechanical disturbances, he has arranged a large number of mortality statistics on the basis of organologic breakdown. In his own words, "the underlying idea of this rearrangement of the causes of death is to put all those lethal entities together which bring about death because of the functional organic breakdown of the same general organ system. The cause of this functional breakdown may be anything whatever in the range of pathology."

When figures showing the relative importance of ten different organ systems in human mortality were arranged for the United States registration area, for

England and Wales, and for São Paulo, Brazil, the relative order of importance of the parts of the organism that first cease to function and cause death was essentially the same in the three cases. Pearl's data show that in the United States, during the period investigated, more deaths resulted from the breakdown of the respiratory system than from the failure of any other organ system of the body. The same thing is true of England and Wales. In São Paulo the alimentary tract takes first position, with the respiratory system a rather close second. The tremendous death rate in São Paulo chargeable to the alimentary tract is chiefly due to the relatively enormous number of deaths of infants under 2 from diarrhea and enteritis. Nothing approaching such a rate for this category as São Paulo shows is known in this country or in England. Pearl points out that in all three localities studied, the respiratory system and the alimentary tract together account for rather more than half of all the deaths biologically classifiable. These are the two organ systems which, while physically internal, come in contact directly at their surfaces with environmental entities (water, food and air) with all their bacterial contamination.

The alimentary canal and the lungs are, in truth, only invaginated surfaces of the body. Along with the skin, they must share the attack of environmental invaders; but the skin, having special protective layers, is naturally more resistant than the mucosa of the other surfaces mentioned. When the protective resistance of these external surfaces of the body fails, the blood and the circulatory system become invaded; hence they stand next in the order of importance in functional breakdown. The complex nervous system is responsible for more deaths than is the excretory system to which the kidneys belong.

Arrangement of the organologically classifiable death rates under the primary germ layers (ectoderm, mesoderm and endoderm), from which the organs concerned develop embryologically, shows that more than half of all biologically classifiable deaths result from a breakdown and failure further to function of organs arising from the endoderm in their embryologic development, while only 8 to 13 per cent. can be regarded as a result of breakdown of organ systems arising from the ectoderm. The remaining 30 to 35 per cent. of the mortality results from failure of mesodermic organs. The fact that mortality grouped in classes that rest on such a biologic basis is, according to Pearl, strikingly similar in such widely dissimilar environments as the United States, England and southern Brazil, is significant. It raises the question as to whether, after all, environment is the predominant factor in human mortality. It is too early to speculate on the hygienic significance of this tentative evidence. It is interesting to note, however, that efforts to improve the public health have of late been directed against affections involving the most prominent groups of organs, the respiratory system

1. Pearl, Raymond: On the Embryological Basis of Human Mortality, *Proc. Nat. Acad. Sc.* 5: 593 (Dec.) 1919.

and the alimentary tract, for which failure of function is a cause of death. In the first of these groups, in which phthisis, lobar pneumonia and bronchitis belong, substantial progress has already been made.

CHARACTERISTICS OF BENCE-JONES PROTEIN

Although many years have elapsed since Bence-Jones first described the appearance of what was long assumed to be an albumose in the urine in certain pathologic cases, the nature of the nitrogenous compound thus excreted has by no means yet been clearly elucidated. The designation "albumose" was due to the peculiar reactions of the substance which seemed to distinguish it from the proteins usually found in pathologic urine. Thus, the Bence-Jones substance is precipitated by salt and heat, much as are coagulable proteins; but frequently it will redissolve when the temperature is further raised, and will reprecipitate on cooling. In view of this, at one time the opinion was ventured that the Bence-Jones "albumose" represented a product of the partial degradation of tissue or blood proteins which is excreted like any proteose.

Subsequent studies in various cases, usually exhibiting multiple myelomas, have made the designation "albumose" untenable and have placed the substance in a class with other simple native proteins. Hence the designation "myelopathic albumosuria" has given way to Bence-Jones proteinuria. Proteoses are toxic when they are introduced to any extent into the blood stream. Taylor¹ and his associates at the University of Pennsylvania Medical School have injected the isolated Bence-Jones protein directly into the circulation of animals without provoking untoward symptoms. Furthermore, the blood of such injected animals clotted normally, which is not the case when true proteoses are introduced.

Even more convincing with respect to the independent identity of the Bence-Jones protein is the fact that, like other individual proteins, it has specific anaphylactic potencies. The Philadelphia investigators first showed this conclusively with protein isolated from the urine of their patient. Recently, Abderhalden² of Halle has actually separated Bence-Jones protein, with characteristic behavior toward heat, from the blood of a person who excreted such a substance into the urine. This blood protein was specific in its anaphylactic reactions. Animals sensitized with it responded with the characteristic "shock" only when the same protein was injected; not to other serum proteins. These facts speak further against the alleged proteose nature of the Bence-Jones substance, for proteoses, as a rule, are not specific antigens in anaphylactic tests.

Whence in the body is this *sui generis* protein, circulating in the blood along with the common plasma proteins and passing the kidney filter when the latter do not pass, derived? There is apparently nothing essentially "foreign" about it, as animals seem to retain and catabolize Bence-Jones protein injected into them in considerable quantity. We can go no further today than summarize the probabilities in the words of recent investigators.¹ The Bence-Jones protein is of endogenous origin and more or less independent of the food intake. It might either be derived from the tumor cells of the myeloma, or be produced through an interrupted or aberrant synthesis of some normal body protein. The biologic indications of close relationship to the normal blood proteins, and the enormous quantities produced would seem to favor the second alternative. The question remains obscure. It is interesting to note that Abderhalden's latest patient showed myeloma-like tumors of the bones at necropsy.

Current Comment

THE AMERICAN MEDICAL DIRECTORY: COOPERATION DESIRED

In 1905, after careful consideration, the Board of Trustees recommended, and the House of Delegates of the American Medical Association approved, the publication of a medical directory, in the belief that such publication would be in the interest of the medical profession. Since that time six editions of the Directory have been issued, and though this has been done at a financial loss, the undertaking has been generally regarded with satisfaction as one of the altruistic enterprises of the Association. At the present time the Seventh Edition is in course of compilation, but under most extreme difficulties. While the price of paper has doubled since the last edition was published, and the labor wage has more than doubled in the last five years, thus enormously increasing the expense, the difficulties to which we refer are not financial. To obtain and classify the data requires a large number of skilled clerical workers. And right here is our difficulty: skilled clerical workers are almost unobtainable at any price, and, in fact, it is impossible to get sufficient ordinary clerical help. This difficulty can be overcome, in part at least, if physicians who receive circulars from our Directory department will promptly respond to the request for data concerning themselves. In most instances this means simply filling out the blanks clearly and returning them. Further aid will be rendered if physicians who have moved during the last two years, or whose names are not correctly listed in the Directory will send corrections at once. We make no apology for this appeal for cooperation because the Directory belongs to the members of the medical profession; it is their Directory. If they cooperate in the manner requested, the difficulties under which the new edition is being issued will be largely removed.

**"CHRISTIAN SCIENCE" AND THE MATERIAL
PRESS AGENT**

The letter from the "Christian Science Committee on Publication" which appears in the Correspondence department of this issue is further evidence of the smooth functioning of the publicity department of the late Mrs. Eddy's organization. Let there appear anywhere a published item that may seem, either directly or remotely, to refer unfavorably to "Christian Science" and forthwith the editor receives a letter from the local "Committee on Publication" supplemented, possibly, with a flood of letters from members of the cult. Woe to the newspaper man who exposes, be it ever so gently, the fallacies of "Science" which is misnamed "Christian." One can but admire the well-oiled publicity machinery of the "Christian Science" organization. Its upkeep must be heavy but it hits on all cylinders. If the medical profession maintained a publicity department that cost a hundredth part of the "Christian Science" press agency, hands would be raised in holy horror and from the house-tops would come the cry: The very foundations of our civil liberties are threatened. Whatever the "Christian Scientists" believe about the immateriality of disease—and just what they do believe is not clear—they are obviously of a mind when it comes to maintaining a material publicity department with material funds.

SPECULATIVE SCIENCE AND ENDOCRINOLOGY

The human body contains a certain number of bones and a certain number of muscles, but nobody knows how many glands. The function of the bones is fairly well understood; the purpose of the muscles is easily comprehended from their structure and action; but our knowledge of the function of all but a few of the glands is in the theory stage. If some one were to suggest that the function of the muscles is to control the will, there would be no lack of evidence to prove that the function of the will is to control the muscles; but when a speculative philosopher arises to remark that the interstitial cells of this or that tissue secrete a hormone whose function it is to govern the duration of life, thousands are ready to give him credence. It is this state of affairs which has called forth the following, which we quote from an editorial in a recent issue of the *British Medical Journal*:

"The speculative philosopher is always with us, and during the last few years has found his chief medical field of activity in the ductless glands and their secretions. Here he has been extremely busy, with the result that the number of such 'glands' has grown almost equal to the number of different tissues in the body; while the number of internal secretions and hormones postulated has become no less enormous. Indeed, it may be said, not unfairly, that with many writers who deal with the subject the only proof of the existence of a hormone nowadays required is that it should seem to be demanded by theory."

There is danger that the great accomplishments in medicine of the last two decades have left the medical mind in too receptive a mood. Some physicians, we

fear, are accepting theories on plausibility rather than on evidence. Such a condition is dangerous, because in such soil the pretender and quasiscientist thrive. "Prove all things; hold fast that which is good" should be the scientific attitude.

PUBLICITY—WITH RESERVATIONS

During the last few years municipal, state and federal departments, whose function it is to protect the public health, have done valuable service by issuing bulletins, periodically, giving information of interest and value to the public. The Department of Health of the City of New York publishes monthly a *Food and Drug Bulletin* which, as the name denotes, deals with the activities of the department in protecting the citizens of New York from fraud in foods and drugs. The information these bulletins contain is interesting and instructive. But it does not go far enough. While describing various cases of fraud or adulteration in food and drugs that occur monthly, the *Bulletin* does not give the names of the offending individuals or firms. We read in a recent issue, for example, that some "well-known biscuit manufacturers" of New York City complained that the 105,000 packages of crackers and biscuits that the Navy Stores were selling to the highest bidder "were moldy, musty, rancid and unfit for human food." Investigation proved that the complaint was without foundation and was "undoubtedly malicious or interested." Why not give the name of the "well-known biscuit manufacturers" who attempted to interfere with the sale of these goods? We read, too, that "a soda water manufacturer in the Bronx" was convicted and fined for using dirty sugar syrup; that in a "cocoanut factory in the Borough of Brooklyn" inspectors found floor sweepings of shredded cocoanut being "reconditioned" and toasted to be put on the market as "Toasted Cocoanut"; that inspectors seized 2,590 pounds of wormy almonds which were being shelled and salted in a nut factory for the market; that the "owners of a large candy factory" were convicted and fined for having 4,000 pounds of unwholesome condensed milk in their possession, intended for use in the manufacture of caramels; that a corporation manufacturing "an inferior grade of compound catsup," having corn-meal as its principal ingredient, was convicted of having 2,150 pounds of unwholesome corn-meal in its manufacturing room; that the owner of a candy factory was fined for having in his possession a quantity of unwholesome prunes and apricots; that a "large baking company" was fined for using wormy raisins in its cakes and another "baking firm" was also fined for using wormy flour in breadstuffs. Then there was the grocer who was fined for offering 7,000 pounds of unsound groceries for sale, and the "large cereal manufacturer" who was fined for packing unclean and contaminated cereals for human consumption. All of these cases are of vital interest to the citizens of New York City and they show that the health department of that city is doing good work. We believe, however, that the greatest deterrent to offenses of this kind is full publicity. To give the public the facts and to avoid casting suspicion on the innocent, the *Bulletin* should publish the names and

addresses of the guilty parties. The fines in such cases are, as a rule, absurdly inadequate, and disproportionate to the profits that may be made by sophistication.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Pasadena Hospital Assured.—The recent campaign for the fund to build a new and greater hospital in Pasadena is reported to have resulted in bona fide subscriptions of more than \$500,000.

New State Officers.—At the annual meeting of the Medical Society of the State of California held in Santa Barbara, May 11 to 13, under the presidency of Dr. Henry A. L. Ryfkogel, San Francisco, Coronado was selected as the next place of meeting, May 10 to 12, 1921, and the following officers were elected: president, Dr. John C. Yates, Coronado; president-elect, Dr. John H. Graves, San Francisco; vice presidents, Drs. William Duffield, Los Angeles, and Joseph H. Catton, San Francisco; secretary, Dr. Saxton T. Pope, San Francisco (reelected).

COLORADO

Postgraduate Lectures.—The lecture teams of the postgraduate lecture course, arranged by the Colorado State Medical Society, attended the monthly meetings of county societies at Canon City, La Junta, Trinidad and Colorado Springs, May 4. This course of lectures, which has been continued through the winter, promises to become very popular. It will be readjusted somewhat and the personnel of the teams changed in some instances, before another year.

Honor to Dr. Work.—The Pueblo County Medical Society gave a banquet at the Minnequa Club, Pueblo, May 7, at which about fifty were present, to Dr. Hubert Work, in honor of his election as president of the American Medical Association. Dr. Herbert A. Black presided as toastmaster and a number of addresses were made. The guest of honor in his response said that his election was a graduation from a course of training which began in the county society and led up through the state society and the national association, and the distinction shown to him was made possible because of the loyalty of the members of his county society.

Congress of Ophthalmology and Oto-Laryngology.—The Colorado Congress of Ophthalmology and Oto-Laryngology will be held in the County Society Assembly Hall, Metropolitan Building, Denver, July 23 and 24, under the auspices of the Colorado Ophthalmological and Colorado Oto-Laryngological societies. Arrangements will be in the charge of a joint committee consisting of Drs. Edward Jackson, Denver; Melville Black, Denver; James J. Pattee, Pueblo; Thomas E. Carmody, Denver; Robert Levy, Denver; William H. Crisp, Denver; Edward R. Neeper, Colorado Springs, and Harry L. Baum, Denver. All ethical practitioners of these specialties are invited to be present.

CONNECTICUT

Health Board for Yale.—The health and sanitary safety of undergraduates of Yale University are hereafter to be guarded by a university board of health patterned after those of great cities. Dr. James C. Greenway, New Haven, will be chairman of the board and will have a staff consisting of physicians and sanitary inspectors. The board of health will make health regulations for the control of students and will undertake personal supervision of their health.

New State Officers.—At the annual meeting of the Connecticut State Medical Society held in New Haven, May 19 and 20, it was decided to hold the meeting for 1921 at Hartford, May 18 and 19, and the following officers were elected: president, Dr. George Blumer, New Haven; vice presidents, Drs. William H. Judson, Danielson, and William H. Donaldson, Fairfield; secretary, Dr. Charles W. Comfort, Jr., New Haven; treasurer, Dr. Phineas H. Ingalls, Hart-

ford; delegates to the American Medical Association, Drs. John E. Lane, New Haven, and Walter R. Steiner, Hartford, and alternates, Drs. Charles J. Bartlett, New Haven, and Frank K. Hallock, Cromwell.

GEORGIA

Medical College Buildings Remodeled.—The buildings of the Atlanta Medical College, opposite Grady Hospital, are to be remodeled at the cost of \$33,360, and when completed will be used as part of the hospital. The trustees of Emory University have offered the buildings to the city, rent free, on condition that students from the medical school of the university be allowed to hold their clinics in the hospital.

ILLINOIS

Medical Society Organized.—Physicians of Moultrie County met in Bethany, April 13 and organized the Moultrie County Medical Society, electing Dr. William P. Davidson, Sullivan, president; Dr. Richard W. Denney, Bethany, vice president, and Dr. Samuel L. Stevens, Dalton City, secretary-treasurer.

Illegal Practitioner Fined.—W. F. Hughey, a magnetic healer at Pana, was arrested by the Department of Registration and Education of the State of Illinois for violating the provisions of the Medical Practice Act and was fined \$50 and costs. The court also compelled Hughey to return a fee of \$42.50 which he had collected the day he was fined from a woman in Pana.

New Sanatorium Building Needed.—The burning of the main building of the Edward Sanatorium, Naperville, crippled the work of the institution and of the Chicago Tuberculosis Institute very materially. The building which was burned housed the bed cases and furnished the examining rooms, laboratories, roentgen-ray rooms, treatment rooms and administration offices of the sanatorium, and was the important center for the cottages.

KENTUCKY

Trachoma Bureau Established.—Kentucky has established a bureau of trachoma and blindness as a part of the state board of health with an appropriation of \$7,500.

All-Time Health Service Provided.—Muhlenberg County has availed itself of the services of an all-time health officer. The cost of this work will be \$10,000 a year, of which \$5,000 is furnished by the federal and state health departments, and \$5,000 by the county.

Honor to Dr. McCormack.—At the ninth annual conference of school, city and county health officers and public health nurses, tribute was paid to Dr. Joseph N. McCormack, Bowling Green, who had served forty years with the state board of health. It was decided that a committee be appointed to arrange for the painting of a portrait of Dr. McCormack to be presented to the health officer with the stipulation that it hang for all time in the executive offices of the state board of health. Dr. Arthur H. Keller, Paris, was made chairman of the committee.

MARYLAND

Anniversary of Association.—The twenty-third anniversary of the Baltimore County Medical Association was celebrated by a banquet held at the Hotel Rennert, Baltimore, May 26. Dr. Junius W. Stephenson of Cornell University was the principal speaker and Dr. John W. Harrison, president of the association, Middleriver, was toastmaster. The other officers of the association are: vice president, Dr. Henry A. Naylor, Pikesville, and secretary-treasurer, Dr. George S. M. Kieffer, Baltimore.

Demonstration to Show Nutritive Value of Milk.—Eight organizations in cooperation with the Women's Civic League of Baltimore gave a demonstration at Osler Hall, May 26, to impress on the public the nutritive value of milk. The National Dairy Council, the United States Department of Agriculture, the state college of agriculture, the city board of health, the public instruction committee of the Medical and Chirurgical faculty, the Johns Hopkins School of Hygiene, the Maryland State Dairymen's Association and the Junior League all were represented. Dr. Mary Sherwood, Dr. William Travis Howard, Jr., Dr. Marion B. Hopkins, Dr. Henry Barton Jacobs and Dr. James H. Mason Knox, Jr., spoke while moving pictures were shown. In the afternoon, Dr. Elmer V. McCollum opened the session, and Dr. William H. Welch, president Munn of the National Dairy Council and Dr. Albert F. Woods, president of the State College of Agriculture, also spoke.

MASSACHUSETTS

Personal.—Dr. William J. Brickley, Boston, has been appointed associate medical examiner (coroner) for Suffolk County, succeeding Dr. Oscar Richardson, resigned.

Advanced Course in Medical Science.—Recognizing the great need for competent specialists in medical science, Harvard Medical School has established a new course leading to the degree of Doctor of Medical Sciences. The first two years of work of this course is substantially identical to that of the regular students, and this work is followed with two years' concentration work in one of the laboratory departments.

MICHIGAN

Hospital Association to Meet.—The annual meeting of the Michigan Hospital Association will be held in Wayne County Medical Building, Detroit, June 8 and 9, under the presidency of Dr. Warren L. Babcock, Grace Hospital, Detroit.

MINNESOTA

Hospital Association to Meet.—The annual meeting of the Minnesota Hospital Association will be held in Duluth the first week in September under the presidency of Dr. Louis B. Baldwin, University of Minnesota Hospital, Minneapolis.

Federation of Public Health Agencies.—A federation of all volunteer public health agencies of Hennepin County was recently incorporated in Minneapolis as the Hennepin County Public Health Association. Each organization will carry on its own particular phase of public health activities and retain its individuality, but the work of all the organizations will be under the supervision of the administration board of the federation, on which each member organization as well as the Minneapolis Health Department is represented. Among the special projects planned are public education, the cure and prevention of cancer, the establishment of free nutritional and dental clinics, the promotion of open-air schools, education in dental hygiene and the establishment of a health center.

MISSOURI

Medical Veterans Organize Society.—The medical and dental officers of St. Joseph who served in the World War held a meeting, May 17, at which they organized with the name "Medical and Dental Veterans of the World War," and elected Dr. William L. Kenney, president.

Personal.—Dr. Leon Paul Forgrave has been elected vice president of the St. Joseph Board of Health, succeeding Dr. Louis J. Dandurant, St. Joseph, resigned.—Dr. Hasbrouck De Lamater, city health officer of St. Joseph, has resigned and has been reappointed director of hygiene in the public schools.

Southwest Missouri Physicians Hold Meeting.—At the annual meeting of the Southwest Missouri Medical Society, held in Springfield, May 21, the following officers were elected: president, Dr. Edward C. Wittwer, Mountain Grove; vice presidents, Drs. Otto C. Horst, Springfield, and Charles H. Orr, Ash Grove; recording secretary, Dr. Edwin F. James, Springfield; corresponding secretary, Dr. Joseph W. Love, Springfield, and treasurer, Dr. Lee Cox, Springfield. The association adopted resolutions in memory of Dr. Herbert Staples Hill, Springfield, for many years secretary of the society.

NEBRASKA

Report of Health Bureau.—The consolidated report of the bureau of public health, November, 1919, shows a total of 380 Wassermann tests on blood and spinal fluid for 1919 under the state venereal law providing for free blood and spinal fluid examinations. More than 190 ampules of arsphenamin were distributed and more than 5,000 cases of venereal diseases were reported by physicians.

New State Officers.—The fifty-second annual meeting of the Nebraska State Medical Association was held in Omaha, May 24 to 26, under the presidency of Dr. H. Winnett Orr, Lincoln. Dr. Miles S. Moore, Gothenburg, was made president-elect; Drs. Ernest A. Creighton, Red Cloud, and Wesley L. Curtis, Lincoln, were elected vice presidents; Dr. Roy D. Bryson, Callaway, was elected councilor for the ninth district; Dr. Norman T. Johnston, Upland, councilor for the tenth district; Dr. Hugh E. Mantor, Sidney, was reelected councilor for eleventh district, and Dr. Alfred J. Stewart, Mitchell, was reelected councilor for the twelfth district; Dr.

Joseph M. Aikin, Omaha, was reelected a delegate to the American Medical Association, and Dr. Willson O. Bridges, Omaha, was elected alternate. The next annual session will be held in Lincoln. One of the features of the meeting was the address by Dr. James L. Greene, Hot Springs, Ark., at the banquet, May 25, on "The Treatment of Neural Syphilis."

NEW JERSEY

Child Hygiene Conference.—The first conference on child hygiene of statewide character, called by the department of health, is to be held by the New Jersey Bureau of Child Hygiene at Asbury Park, June 12 to 14. The New Jersey legislature has granted the largest appropriation ever made by a state for this purpose—\$150,000.

NEW YORK

Chiropractic Bill Vetoed.—It is reported that Governor Smith of New York has vetoed the bill recently passed by the New York legislature providing for a separate board of chiropractors.

Amendment to Labor Law.—An amendment to the labor law, passed by the legislature at its last session, provides that after July 1, 1920, children employed in mercantile establishments shall be subject to physical examinations of the same kind required in the case of children working in factories. These examinations are to be made by medical inspectors on the staff of the state industrial commission.

New York Hopes to Deport Alien Insane.—It is estimated that about 800 alien insane who are being cared for by the institutions of this state will be deported with the 6,000 alien insane in this country whom the United States Bureau of Immigration is planning to send back to Europe. The sending back to their home countries of these patients will greatly relieve the congestion in the institutions for the insane in this state.

Removal of Prohibition Restriction.—The Medical Society of the County of Rensselaer at its last meeting adopted a resolution that representatives in Congress be requested to introduce a bill to amend Section 7 of the National Prohibition Act to the end that the restrictions contained therein as to the amount of spirituous liquor, beer or light wine that may be prescribed for the use of any patient may be removed or modified, and appointing a committee with instructions to confer with medical societies of the state and throughout the United States to secure concerted action and to provide for ways and means to bring to the attention of Congress the desirability of the proposed amendment.

New York City

Personal.—Dr. Simon Flexner of the Rockefeller institute has been elected an associate member of the French Society of Tropical Pathology.

Hospital Drive Extended.—The campaign to raise \$2,000,000 for the New York Post-Graduate Medical School and Hospital will be continued through the summer. Among the recent gifts were \$10,000 from Mrs. E. H. Harriman, \$1,000 from Mrs. J. Henry Watson, \$1,000 from the employees of the Brooklyn Rapid Transit Company and \$500 from the Allis-Chalmers Manufacturing Company. The fund on May 28 totaled \$1,277,176.57.

Health Organization of America Offers Fellowship.—This organization offers one year in Teachers College, Columbia University (September, 1920, to June, 1921) for the study of modern health education in the elementary schools, to be awarded for the best graded plan and outline for interesting children in the establishment of health habits. Details will be furnished on application to the Child Health Organization of America, 156 Fifth Avenue, New York City.

Health Department Tests Accuracy of Thermometers.—The sanitary bureau of the department of health has made a survey of a number of clinical thermometer manufacturers in and out of the city and has submitted reports. To demonstrate to physicians and nurses the utter worthlessness of some of the thermometers on which they have been depending, 156 clinical thermometers taken from physicians and nurses were tested. Of these, eighty-four, or 54 per cent., were found defective, while seventy-two, or 46 per cent., were found acceptable. No repeated reading could be made, and all tests necessary to determine the accuracy of the thermometers were not carried out in full; hence it is probable that some of the thermometers passed would prove defective if subjected to all the tests which are necessary to determine a good thermometer. In view of the results

of these tests, an appropriate amendment to the sanitary code and regulations to govern the selling, holding or keeping for sale of clinical thermometers in this city is under consideration by the department of health.

NORTH CAROLINA

Hospital Association Elects Officers.—At the annual meeting of the North Carolina Hospital Association, Dr. James M. Parrott, Kinston, was elected president, and Dr. John Q. Myers, Charlotte, secretary and treasurer.

Public Health Work for State Society.—A special committee appointed at the recent meeting of the state medical society has made its report urging that a permanent committee be named to prepare a plan for public health administration.

Personal.—Dr. Andrew J. Crowell, Charlotte, has been appointed a member of the state board of health, succeeding Dr. Edward C. Register, deceased.—Dr. Dan E. Sevier, Asheville, has been elected a member of the state board of medical examiners for nurses, succeeding Dr. Thompson Frazier, term expired.—Dr. Margery J. Lord, Asheville, has been appointed a missionary to the Presbyterian board and assigned to duty as a medical missionary in the Belgian Congo, West Africa.

OHIO

Cabot in Fremont.—Dr. Hugh Cabot of the University of Michigan spoke before the Toledo Academy of Medicine, May 14, on "Appendicitis."

State Public Health Organization.—A new association was organized at Columbus, May 12, known as the Ohio Public Health Association and the following officers were elected: president, Dr. Chester B. Bliss, Sandusky; vice presidents, Dr. Lucian G. Locke, Portsmouth, and Mrs. W. C. Marshall, Selma; secretary, Dr. Robert G. Patterson, Columbus, and treasurer, Mr. Theodore S. Hunter, Columbus.

Personal.—Dr. Kell M. Ellsworth, Dayton, was found in his home, May 19, suffering from a knife wound of the throat, and is under treatment in the Miami Valley Hospital.—Dr. Elwood Miller, Springfield, has been elected superintendent of the District Tuberculosis Hospital in that city, succeeding Dr. Rush R. Richison, who resigned to accept the position of health officer of Springfield and Clark County.—Dr. Dallas K. Jones, Wooster, has been appointed health commissioner of Wayne County.

Academy Activities.—On May 14, Dr. Charles Claude Guthrie, professor of physiology and pharmacy of the University of Pittsburgh School of Medicine, made a report before the one hundred and second regular meeting of the experimental medicine section of the Cleveland Academy of Medicine on "Experimental Studies on the Heart with Particular Reference to Fundamental Properties of Heart Tissue and Their Power on the Interpretation of Surgical Functional Disorders."—At the regular meeting, May 28, Dr. Thomas W. Salmon, New York City, medical director of the National Committee for Mental Hygiene, spoke on "What a Psychiatric Clinic Can Do for Cleveland." In his remarks, he stated that Cleveland has approximately 8,000 insane and feeble-minded in need of hospital care, and that it has no provisions for the care of these persons. He recommends that the state provide 2,000 more hospital beds for the insane; a hospital for the feeble-minded with a capacity of 2,000; 200 beds at the city hospital for handling the nervous cases; three mental clinics at the Lakeside and city hospitals and a location near the public square.

Illegal Practitioners Convicted.—The Ohio State Medical Board reports that five persons were convicted of practicing medicine in that state without licenses: Helen Platz, Cleveland, previously convicted of illegal practice of medicine, rearrested and after hearing in Euclid Township on May 10 was bound over to the grand jury.—A. B. Foster (unlicensed), Cleveland, arrested and convicted of illegal practice of medicine on May 11. It being the second offense, he was given a jury trial before Judge Terrell and a sentence of \$500 and six months in the workhouse was imposed.—"Dr." Clarmax Gillum (unlicensed), Cleveland, convicted in the Municipal Court of Cleveland and fined \$100 and costs and told to leave the city.—Mrs. Erato Zacharatos, Canton, pleaded guilty in the Probate Court of Canton, on May 13, to practicing medicine without a license and was fined \$25 and costs.—Mike Boldis, Akron, arrested on May 13 for illegal practice of medicine, pleaded guilty before Judge O'Neil in the Municipal Court of Akron and was fined \$100 and costs.—Dr. R. M. Sproul, Lima, charged with furnish-

ing 70 grains of chloral hydrate to an alleged drug addict, is said to have pleaded guilty and to have been fined \$100, May 7. The defendant stated that he had been practicing without a license since 1902 and was ignorant of the fact that a state license was required.

OKLAHOMA

New Hospital Association Officers.—The annual meeting of the Oklahoma State Hospital Association was held in Oklahoma City, May 19, and the following officers were elected: president, Dr. Fred S. Clinton, Oklahoma Hospital, Tulsa; vice presidents, Drs. John A. Hatchett, El Reno Sanitarium, El Reno, and Arthur S. Risser, Blackwell Hospital, Blackwell; executive secretary, Mr. Paul H. Fessler, University Hospital, Oklahoma City; treasurer, Dr. John H. White, Muskogee Baptist Hospital, Muskogee; delegate to the American Hospital Association, Dr. Charles L. Reeder, Tulsa Hospital, Tulsa, and alternate, Dr. George A. Boyle, Enid Hospital, Enid.

PENNSYLVANIA

Health Code to Protect Water Supply.—Private corporations, acting in a public or quasi public capacity, are directly affected by a new sanitary code which the advisory board of the state health department has adopted. The new sanitary code, drafted by Chief Engineer Charles A. Emerson, Jr., of the state health department, is included in a complete revision of the orders and regulations of the advisory board.

Philadelphia

Jefferson Commencement.—The ninety-fifth annual commencement of Jefferson Medical College was held at the Academy of Music at noon Saturday, June 5. Admiral William C. Braisted, Surgeon-General, U. S. Navy, delivered the valedictory address, his subject being "Joseph and Benjamin or Scientific Opportunities and Civic Obligations." There were 165 in the graduating class.

Memorial Tablet.—In the front hall of the Jefferson Medical College, a bronze memorial tablet was erected by the class of 1919, bearing the following inscription:

The Jefferson Medical College. The Class of 1919 has erected this tablet to Commemorate the Military Service of 1,187 Commissioned Officers of the Medical Corps of the Army and Navy, 431 Enlisted Men of the Students' Army Training Corps and an Unknown Additional Number of Other Graduates and Undergraduates of the Jefferson Medical College who, in the World War, Served their Country's Cause on Every Field, to their Own Credit and the Added Glory of their Alma Mater.

Personal.—Dr. E. B. Krumbhaar, Flourtown, has been appointed director of the pathologic laboratory of the Philadelphia General Hospital and clinical pathologist in the Bureau of Hospitals.—Dr. J. E. Burnett Buckenham has resigned as superintendent of the Municipal Hospital for Contagious Diseases.—Dr. Edgar Fahs Smith, retiring provost of the University of Pennsylvania, was a guest of honor at a dinner given by nearly 500 members of the faculty of the University of Pennsylvania at Weightman Hall, May 26.

TENNESSEE

Personal.—Dr. Willis S. Alexander was elected mayor of Ridgely, May 5.—Dr. Stanton H. Barrett has resigned as city director of health at Chattanooga.—Dr. Edward B. Wise, Chattanooga, has been appointed city physician of Chattanooga.

Charter Asked for Health Clinics.—Application has been filed for a charter for the Knoxville Health and Welfare Association. The future home of the association is to be in the McClung Building and will be ready for occupancy July 1, and will house the children's free clinic, the state anti-tuberculosis clinic, the American Red Cross general clinic and the United States Public Health Service.

VIRGINIA

Children's Hospital.—The Dooley Hospital, Richmond, recently constructed at a cost of \$55,000 and to be devoted exclusively to children, has recently been opened. It has a capacity of forty-two patients.

Appropriation for Health Work.—The Board of Supervisors of Henry County have voted an appropriation of \$5,000 to place the county in line for a year's cooperative health campaign with the state board of health on the county unit plan.

Tuberculosis Clinics.—The series of clinics held in Prince Edward County, by the Virginia Tuberculosis Association,

were crowded to their capacity. Dr. Dean B. Cole, Richmond, medical director of the association, and his assistants examined 255 persons who applied, of whom 166 were white and sixty-nine colored. Of the total number examined, 200 gave negative results.

To Guard Health of State Prisoners.—The board of directors of the penitentiary, Richmond, passed resolutions, May 4, looking to the improvement of conditions in the medical systems of the state prisons. These provided that the president of the board of directors of the penitentiary draw up, for adoption by the board of medical examiners, forms to be used by the surgeons of the penitentiary and state farm in examining convicts on admission and on release, and directed the surgeons to make a thorough examination of every person now at these institutions and hereafter, within forty-eight hours after admission, to make a similar examination of every prisoner at these institutions, and furthermore to make a similar examination of every prisoner before release and to record the findings in detail on the forms furnished by the board.

CANADA

University News.—Queen's Medical College, Kingston, Ont., is preparing for a forward movement. All salaries have been increased and six new professors added. The general hospital is to be enlarged. It is now thought that it will not be necessary to remove to Ottawa which was a live question a few months ago. About a million dollars is now in sight for improving the general hospital.

Personal.—Dr. H. C. Cruickshank, who served twelve months overseas and was wounded, has been appointed director of laboratories, medical department of health, Toronto. —Dr. Dowell Young of Cornell University has been appointed professor of biology in Dalhousie University, Halifax, in place of Prof. C. Moore, resigned. —Dr. J. W. Ross is Canadian Government Commissioner in China. —Dr. Joseph Edwards Midgley, formerly of St. Thomas and St. Mary's, Ont., but recently of Brooklyn, has returned to Canada and will probably practice in Toronto. —Dr. Samuel H. McCoy, formerly of St. Catharines, Ont., and Toronto, after returning from overseas, is at present in Ottawa, where he is working on the Canadian medical history of the war.

Ontario Medical Association.—The annual meeting of the Ontario Medical Association was held in Toronto, May 25 to 29. Work was commenced by the board of general purposes having a conference, and as this is composed of representatives from the city and county societies it is now considered an important body. Some of their recommendations were: that special classes should be established by school boards for the training of mentally defective; that there should be stringent immigration laws to prohibit the bringing in of mental defectives, legislation to prevent their marriage, and better education of medical students on the subject of psychiatry; a recommendation that the number of government liquor dispensaries in Ontario should be increased (now seven in Ontario) and that these stores should be kept open Saturday afternoons and Sundays. President Frederick W. Marlow, Toronto, regretted the lack of attendance at medical meetings. He said that there should be some law to compel medical men to take either graduate courses from time to time, or to compel their attendance at the medical meeting. There was something wrong in a system that allowed a man to graduate and then go along as he wished for many years whether he studied or not. He emphasized the need of more hospital accommodations as well as more nurses. That he did not mention the need of more physicians suggests that there are now enough and to spare. Dr. Nelson W. Percy, Chicago, associate professor of clinical surgery, University of Illinois, read a paper on the transfusion of blood which should be carried out after careful selection of the donor. He dealt with its use in pernicious anemia. Dr. Edward C. Rosenow, Mayo Clinic, Rochester, Minn., delivered an illustrated address on experiments in influenza, which was much appreciated. Dr. Charles W. Service, Chengtu, West China, addressed the meeting on the medical needs of China, particularly on insanitary conditions which were the greatest problem in health matters there. There was widespread disease due to neglect, poverty and ignorance which ran the death rate to 40 to 50 per thousand in adults and from 50 to 70 per thousand in children. He appealed particularly for interest in the West China Medical School. Higher fees for insurance examinations was a live topic of discussion. In the various sections the papers were listened to with keen appreciation and elicited much

discussion. The following officers were elected: president, Dr. James Huerner Mullin, Hamilton; vice presidents, Drs. Frank J. Farley, Trenton, and Frederick Arnold Clarkson, Toronto; secretary-treasurer, Dr. Thomas C. Routley, Toronto.

GENERAL

Mary Putnam Jacobi Fellowship.—The Mary Putnam Jacobi Fellowship for 1920-1921 has been awarded to Dr. Sophie Getzowa of the University of Berne, Switzerland.

American Association for Advancement of Science.—The 1922 meeting of the American Association for the Advancement of Science and Affiliated and Associated Societies will be held in Toronto, Ont., during the Christmas holidays of 1921, under the auspices of the city of Toronto, University of Toronto and Royal Canadian Institute.

Gastro-Enterologists Elect Officers.—At the annual meeting of the American Gastro-Enterological Society held in Atlantic City, May 3 and 4, the following officers were elected: Dr. Joseph Sailer, Philadelphia, president; Drs. Allen A. Jones, Buffalo, and James C. Johnson, Atlanta, Ga., vice presidents; Dr. Frank Smithies, Chicago, secretary (reelected); Dr. Horace W. Soper, St. Louis; recorder, and Dr. Clement R. Jones, Pittsburgh, treasurer.

Surgeons Elect Officers.—At the forty-first annual meeting of the American Surgical Association held in St. Louis, May 3 to 5, under the presidency of Dr. George E. Brewer, New York City, the following officers were elected: president, Dr. John B. Roberts, Philadelphia; vice presidents, Drs. Harvey G. Mudd, St. Louis, and James F. Mitchell, Washington, D. C.; secretary, Dr. John H. Gibbon, Philadelphia (reelected); treasurer, Dr. Charles H. Peck, New York City, and recorder, Dr. John H. Jopson, Philadelphia (reelected).

Conference of State and Territorial Health Officers with the Surgeon-General of the U. S. Public Health Service.—At the annual conference of state health officers with the U. S. Public Health Service, held in Washington, D. C., May 26 and 27, it was recommended that the Conference adopt the Standard Railway Code outlined through its committee. The following resolution was added:

Resolved, That any laws concerning the sanitation of public conveyances and public railway stations should contain a clause penalizing the public for befouling such conveyances and such stations, for we recognize that unclean and befouled public conveyances and stations are made so by dirty people and they should be penalized for their filth.

Relative to the bill H. R. 10925 S. 3250 (known as the Sheppard-Towner Bill) making provision for promoting the care of maternity and infancy in the several states, and the new federal and state health agencies known as "A Federal Board of Maternal and Infant Hygiene" and "State Boards of Maternal and Infant Hygiene," thereby created, it was stated that the establishment of new or competing health organizations, federal or state, weakens the efforts of the existing legally constituted health agencies. It was therefore

Resolved, That it is the sense of the Eighteenth Annual Conference of the State and Territorial Health Authorities with the United States Public Health Service that the objects of the Sheppard-Towner bill for the public protection of infant and maternal life be strongly endorsed; and,

Resolved further, That it is the sense of this conference that the Federal administration of this act should be under the supervision and control of the Public Health Service, and in states, of the state health authorities; and that the sections of said bill relating to administration be changed to accord with these suggestions; and,

Resolved further, That this resolution be laid before the committees on education and labor of the House and Senate by a special committee representing this conference.

A resolution on rural health work was introduced by the statement that over 53 per cent. of the population of the United States is rural and the food supply for our whole nation is dependent on production in the rural districts. Physical defectiveness and preventable diseases have been found by extensive careful studies to be as prevalent in our rural as in our urban population and only about 3 per cent. of our rural population is served by local whole-time health departments approaching adequacy. The application of the principle of federal aid extension to rural health promotion appears entirely logical, consistent with the theory and established practices of our system of government and is urgently needed at this time. A resolution was adopted endorsing the principles of legislation contemplated by the Lever Rural Health Bill introduced in the Sixty-Sixth Congress and agreeing to advocate such principles with a view to bringing about a nation-wide popular demand on the Congress of the United States for such legislation.

LATIN AMERICA

Nicaraguan Asylum for Paupers and Feeble-minded.—There was opened recently, at Managua, an asylum for paupers and demented.

Plague in Mexico.—It is stated from Mexico that there have occurred several cases of bubonic plague in the port of Vera Cruz, and President Wilson has offered to send hospital ships, physicians, nurses and medical supplies immediately.

New Medical Posts in Cuba.—The department of public instruction of Cuba has ordered the appointment of assistants to three chairs in the medical school, namely, medical pathology, practical pharmacology and therapeutics applied to stomatology.

School of Odontology in Uruguay.—There has been established in Uruguay a school of odontology connected with the faculty of medicine. The preparatory studies will be the same required for entrance to the school of medicine. The course in odontology will last four years.

Personal.—Dr. Henrique da Rocha-Lima has returned to Rio de Janeiro from Germany, where for several years he has been privat-docent for tropical diseases at the Institute for Ship and Tropical Diseases at Hamburg.—Dr. Henrique Molina has been appointed rector of the University of Chile. He has recently spent two years in research in this country. His published works include "Philosophia americana" and a refutation of Bergson's theories.

Plague in Brazil.—The *Brazil Medico* states that the local authorities of the state of Rio Grande do Sul have informed the central government that there is no need for outside help to combat the plague as no new cases have been reported for more than a month in the seven stations along the railroad where sporadic cases had developed, a total of nineteen in all. The contagion was traced to a cargo of grain at Uruguayana and here there were forty cases, but no new cases for a few weeks have been discovered, and the disease nowhere assumed epidemic form. The Rockefeller Foundation is organizing a hookworm campaign in that state in cooperation with the local health authorities.

FOREIGN

Gift for Bacteriologic Research.—Our French exchanges relate that "Mr. M. Douglas Flattery, an American philanthropist, has presented the Institute of Bacteriology at Lyons with 100,000 francs for an annual scholarship for a student who will specialize in laboratory work on the bacteriology of infectious diseases."

Suspension of Ophthalmologic Journal.—It is announced that the *Zentralblatt für Augenheilkunde*, founded and edited by Prof. J. Hirschberg for forty-three years, is to suspend publication. Michel's (formerly Nagel's) *Jahresberichte über die Leistungen und Fortschritte im Gebiete der Ophthalmologie* is also to stop publication with 1920. The back numbers from 1914 are to be made up to the current year.

Suspension of the "Archives de Médecine Expérimentale."—The Archives founded by Charcot for recording research in experimental medicine and pathologic anatomy now announces that with the close of the twenty-eighth volume it suspends publication. Its swan song is an article by Garnier and Reilly on the anatomic findings in various organs with acute yellow atrophy of the liver; Catsaras' study of metastasis by retrograde lymphatic routes; an account of experimental research by Achard, Leblanc and Binet on the blood changes during carbon oxychlorid poisoning, and of Achard and Gaillard's experimental research on various flours.

Deaths in the Profession in Other Countries

Sir Henry Burdett, London, founder and editor of the *Hospital and Nursing Mirror*, author of Burdett's "Hospitals and Charities," the "Hospitals and Asylums of the World," "Official Nursing Directory" and many other works on hospitals, medical sociology, and fiscal matters, aged 73, died recently.—Dr. A. Pasteur of Geneva, aged 90.—Dr. Sarda, professor of forensic medicine at the University of Montpellier, aged 66.—Dr. Julio Palma, professor of histology at Bahia, Brazil, until retired.—Dr. J. O. de Azevedo of the chair of medical chemistry in the same faculty. He was also deputy from the province.—Dr. G. Marchetti of Brescia, Italy, succumbed to smallpox contracted professionally.—Dr. A. Ceradini, director of the Laboratorio Micrografico Municipale of Milan and president of the Reale Società di Igiene.—Dr. F. Camaggio, instructor in surgical anatomy at the University of Naples.—Dr. R. Livi, instructor in anthropology at the University of Rome.

Government Services

Banquet to Admiral Barber

The officers on duty and the patient officers at the naval hospital, Fort Lyon, Colo., gave a banquet, April 29, to Rear Admiral George H. Barber, M. C., U. S. Navy, on his retirement from command of the hospital.

Honorary Degrees to Admirals Braisted and Stitt

Rear Admiral William C. Braisted, Surgeon-General, U. S. Navy, delivered the principal address at the ninety-fifth commencement exercises of Jefferson Medical College, June 5. The college conferred the honorary degree of LL.D. on Admiral Braisted, and the honorary degree of D.Sc. on Rear Admiral Edward R. Stitt, M. C., U. S. Navy, head of the naval medical school.

French Surgeons Honored

General Tuffier, chief surgeon of the French Army, who was delegated to represent the French government at the American Surgical Congress in St. Louis, was the guest of honor at a luncheon given by Dr. James F. Mitchell at the Metropolitan Club, Washington, May 8, at which Major-General Merritte W. Ireland, Surgeon-General, U. S. Army; Rear Admiral William C. Braisted, Surgeon-General, U. S. Navy, and Colonels Mathew A. Delaney and William H. Moncrief, M. C., U. S. Army, Dr. Livingston Farrand, director of the American Red Cross, and Dr. John M. T. Finney of Johns Hopkins University were also present.

Health Conditions of the Army

The incidence of communicable diseases is slightly lower than last week, although the admission and noneffective rates are about the same. There were only twenty-five new cases of measles reported from all stations during the week; one new case of scarlet fever reported from Camp Taylor, and one from the Western Department. Camp Dix reports one new case of diphtheria and Brooks Field, Texas, reports the admission of five diphtheria carriers. The Southern Department reports twelve admissions for malaria, seven of which were at Brownsville. Camp Upton is the only large camp reporting a case of pneumonia. The death rate for disease, 4.3, is considerably higher than last week although but fourteen deaths from disease were reported. Tuberculosis was reported as the cause of six deaths and pneumonia of two.

New Legislation for Army Medical Corps

Surgeon-General Ireland states that 1,000 additional medical officers will be required in the Army, under the provisions of the Army Reorganization Bill which has just been agreed to in conference by the Senate and House committees. This new legislation provides for a commissioned personnel in the Medical Corps numbering 1,820. The Army has, at the present time, only about 800 medical officers.

This new Army legislation has been drafted with the view of attracting medical men of the highest character and qualifications to the Army, and offering unusual inducements to them after they have entered.

Physicians who are now in the Medical Reserve Corps and who served during the World War can reenter the Regular Army up to the age of 58 years.

No person below the age of 48 can be appointed in the grade of colonel, or below the age of 45 in the grade of lieutenant-colonel, or below the age of 36 in the grade of major. Appointments in the grade of first lieutenant shall be made from the Medical Reserve Officers between the ages of 23 and 32; and in the grade of second lieutenant from enlisted men of the Medical Department between the same ages, who have had at least two years' service.

The bill provides that hereafter an officer in the Medical Corps shall be promoted to the grade of captain after three years' service, to the grade of major after twelve years' service, to the grade of lieutenant-colonel after twenty years' service and to the grade of colonel after twenty-six years' service.

The new legislation gives to the commissioned officers of the Medical Corps permission to attend technical, professional

and educational institutions and hospitals for special training at government expense. Such privilege has never been heretofore accorded medical officers, although it has been granted by legislation to the engineers, artillery and other corps of the Army. The bill permits 2 per cent. of medical officers to have the privilege of this special training at educational institutions and hospitals each year. Heretofore medical officers who desired to undertake special study or investigation of the latest development of medical science were given leave of absence for a few months each year, and the cost of tuition at educational institutions was paid by the individual officer.

Surgeon-General Ireland looks on this provision of the new legislation with much approval and is confident that it will be of practical benefit to medical officers.

The bill also provides special inducements to the enlisted men in the medical department by providing that the Medical Administrative Corps shall be composed of men from the enlisted service who may become commissioned officers in the grades of captain and first lieutenant after five years' enlisted service.

The bill authorizes the Secretary of War to maintain military training camps during fixed periods each year. It is the intention of the Surgeon-General to utilize the services of officers in the Medical Reserve Corps at these training camps, where theoretical and practical instruction may be imparted to such officers along military lines.

In this way, medical reserve officers will have special training in the event a national emergency should require their call to the regular service.

It is likely that this Army bill will go to the President for signature early in June.

Infanticide and Professional Secrecy

A midwife was prosecuted in the court of correction at Vesoul because of her failure to give prescribed notice to the civil authorities of the birth of an infant. The midwife had been called by telegraph, but arrived on the scene twelve hours after delivery of the child. The young mother confessed that she had strangled the newborn infant, and the midwife consequently confined her efforts to delivery of the placenta. This fact was used in her legal argument that she had not "attended the delivery of the child." The French laws impose on the physician, midwife or any other attendant at a confinement, the duty of reporting the birth of a child, in absence of the father, but the judicial penalty is not applicable unless the defendant has attended the birth. The court did not concur in the opinion of the midwife, but decided that any person who assists at the various phases of confinement, especially delivery of the child and the placenta, must be considered an attendant at childbirth. The midwife also raised the further objection that she could not legally make the notification because she would thereby have revealed the infanticide. Having learned of this crime through confession of the patient and in the exercise of professional duty, she was held to professional secrecy which would have been violated by giving notice of the birth. The court, not agreeing with the view, held that the scruple of not denouncing the patient was inadmissible for the reason that the obliga-

tion of birth notification rested on physicians and midwives with the same severity as on all other attendants, even though such notification might lead to discovery of a crime. The midwife was therefore sentenced to pay a fine.

Prophylaxis of Diphtheria

The prevention of diphtheria was the subject of discussion at the last meeting of the Société de Pédiatrie. A committee appointed to make a study of the question has expressed regret that present sanitary legislation does not place effective weapons at the disposal of the health officers. The report led to an interesting discussion, in the course of which Dr. J. Comby remarked that in spite of serotherapy, diphtheria was still responsible for a considerable mortality in Europe and elsewhere. For some years no progress has been made in serotherapy and Comby thinks that by preventive measures should be sought the success not hitherto attained by serotherapy. On the other hand, disinfection is difficult and vexatious.

Dr. Louis Martin claimed that Comby showed himself a decided pessimist in his evaluation of serotherapy; before the days of antitoxin, there were 1,432 deaths per annum from diphtheria, whereas the present rate is 331. Curves plotted for five-year periods will show a steady decline, and, notable fact, in those countries with the most favorable rates, Holland and Belgium, the serum is distributed gratis.

Dr. Apert called attention to the great danger encountered by always treating the same diseases in the same wards; particularly resistant strains of micro-organisms are thus developed, an observation which was confirmed by Barbier.

Fees of Attending Physicians at Duels

Can a physician legally claim a fee for attendance on a principal in a duel? This question was submitted to a Paris justice of the peace by Dr. Logeais, who was called to attend one of the principals in a duel several months ago. The justice replied in the negative, for since the duel was an illegal act, it could not be made the basis of a legal action.

Laënnec Institute

A committee which was formed several months ago for a study of the best means of commemorating the centenary of the inventor of auscultation has decided on the creation of a Laënnec institute for the study, prevention and treatment of tuberculosis. Its principal activities will be the establishment of laboratories, dispensaries and sanatoriums, the organization of campaigns in France and abroad, and similar endeavors. The statutes of the institute have recently been adopted by the constituent general assembly which at the same time appointed the administrative council, the bureau of which consists of Professor Letulle, president, and Professors Gley, Calmette, Vaquez and Dr. Sergent, vice presidents.

The Income Tax and the Birth Rate

The Conseil supérieur de la Natalité has recommended to parliament that the exemption from income tax be fixed at 4,500 francs for unmarried, and at double that figure for married persons. It is also asked that the exemption prescribed for each child in a family be doubled for the fifth and each succeeding child.

A National Institute of Hygiene

At the last session of the council of the University of Paris approval was given to an arrangement between M. J.-L. Bréton, minister of hygiene, and Professor Roger, dean of the medical faculty, acting on behalf of the minister of public instruction. The agreement promises creation by the minister of hygiene of a national institute designed for the instruction of students in all matters pertaining to hygiene,

for the training of specialists in hygiene and of nonmedical technicians, and finally for the development by every possible means of scientific research as applied to hygiene.

Physiology of the White Man in the Tropics

The Australian Institute of Tropical Medicine is studying the effect of exercise under the influence of humidity and high temperature of nature. Previous experiments of this kind have been made only under artificial conditions. The problem was to ascertain whether the white man in the tropics reacts in a similar manner to heat exposure, at rest and at exercise, as in a temperate climate. In other words, does life in the tropics bring about a new adjustment (acclimatization)? It was found that slow exercise greatly increased the metabolism for a short period, but that a point was reached after which the rate of increase was much smaller. On walking 2 miles, the body temperature rose considerably (from 2 to 3 degrees), the blood pressure increased from 10 to 20 mm. of mercury, and the pulse rate from 20 to 37. This took place during the first half of the walk. But after the second half of the walk the temperature and pulse showed a much slighter increase, and the blood pressure even decreased. The decrease was probably brought about by dilatation of the superficial veins, which withdrew blood from the arterial system. Vigorous exercise for a short period—two or three minutes—increased the metabolism enormously, but the organism soon returned to normal, and the rectal temperature was not affected to any extent. Much greater increase of temperature was brought about by exercise than in a temperate climate because the high temperature and the humidity of the tropics interfered with the cooling mechanism. The experiments showed that it was impossible to continue heavy manual labor under tropical conditions for the same time as in a temperate region without raising the body temperature to a dangerous degree.

Shell Shock and Court-Martials for Cowardice

In the House of Lords an important debate took place on this subject. Lord Southborough called attention to the different types of hysteria and traumatic neurosis, commonly called shell shock, from which many soldiers suffered during the war; referred to the death penalty inflicted on men for cowardice, and moved that inquiry should be made into the expert knowledge derived by army medical authorities with the object of recording for use in time to come the experience of the war and advising whether some scientific method of dealing with such cases could not be devised. He said that it was now recognized that shell shock cases were examples of varying types of hysteria and traumatic neurosis. It was not confined to the untrained soldier, but was common in seasoned soldiers marked out for bravery. With regard to cases of dereliction of duty followed by court-martial and sometimes the death penalty, the evidence given in these cases should be examined in secret and the question considered whether some other course should not have been taken with regard to some of the men. Lord Horne, as an experienced general officer, supported the motion. From his personal knowledge he could say that if in the early days of the war there might have been cases of injustice, he confidently asserted that if there was a shadow of doubt or any suspicion that the crime committed had been caused by any form of hysteria, the result of shell shock, the sentence would not be confirmed until the accused had been under the observation of the medical authorities.

Viscount Peel, undersecretary for war, replying for the government, said that no doubt in former wars there were cases of shell shock, but they were not recognized as such. He was unable to say whether during the late war cases of injustice occurred; but immense trouble was taken at court-martial and in the subsequent proceedings that no one should be condemned to death unless for the gravest, most serious reasons and unless all morbid causes had been eliminated. When a soldier in his defense or in mitigation of punishment urged a substantial plea on mental grounds, medical witnesses were called, the court-martial was adjourned, and a medical board was held. At the adjourned meeting one or more members of the board were called as witnesses to give evidence as to the effects observed. A mental specialist was always included in the board. If there was the slightest ground for further inquiry, headquarters ordered a medical board to examine and report before any action was taken to confirm the death sentence. No sentence of death was carried out until confirmed by the commander-in-chief, who invariably consulted the judge advocate-general. Eighty-nine per cent. of the death sentences pronounced were commuted by the commander-in-chief. The total number carried out during the war was exceedingly small. Most of them were accounted for by cowardice (eighteen cases) and desertion (266 cases). The view of the government was that great advantage might be obtained by such an inquiry as was suggested. Many of the nervous and mental conditions encountered were entirely new to the medical officers. The motion was agreed to.

Struggle Between the Government and the Profession in Tasmania

The case of Victor Richard Ratten, a physician who obtained admission to the medical register of Tasmania by means of a diploma stated to have been granted by a defunct American medical school, has been previously discussed in *THE JOURNAL*. He incurred professional odium by remaining in government employment on the staff of a hospital on terms which the Tasmanian branch of the British Medical Association declared to be unacceptable to the profession. An inquiry into his credentials was then begun by the medical council. It was evidently regarded by the government as simply a move in the struggle between itself and the profession, for an act has been passed which deprives the council of the power to remove from the medical register physicians who have committed offenses or have obtained registration by fraud. The council can apply to the supreme court or to a judge for this purpose. The *Medical Journal of Australia* accuses the government of passing this act with a view to the particular case of Ratten. The medical council had been instructed by the Premier to investigate his case, but the act prevents the council from pursuing the inquiry beyond the limits prescribed by the government. The act also strikes at the profession in another way. Certain physicians have disregarded the resolutions of their colleagues by continuing to treat well-to-do persons in charitable institutions. The result was that their colleagues refused to meet them in consultation. The act provides that if any registered physician without reasonable excuse (the proof of such reasonable excuse being on him) refuses to consult with or render professional assistance in consultation to any other registered physician seeking such advice or assistance, he shall be guilty of an offense for which the penalty is not less than \$250 or more than \$1,000. It is expressly stated that "the expression 'reasonable excuse' shall not include any resolution or by-law or any agreement of any company, association or body of persons." Further, the act states that "any person, association, company or body of persons who, directly or indirectly, prevents or endeavors to prevent or aid in prevent-

ing in any way whatsoever any physician or nurse, or other person applying for appointment, accepting or holding any appointment in any state-aided hospital or charitable institution, shall be guilty of an offense for which the penalty is not less than \$125 or more than \$1,000. The Tasmanian branch of the British Medical Association is thus liable to be fined for an act which it is constantly doing. A result is that its official organ, the *Medical Journal of Australia*, has had to remove from its pages a notice requesting physicians to communicate with the honorary secretary of the branch before applying for certain government appointments. The *Journal* adds, however, that this will not help the government, for there is not a physician in the commonwealth who is not fully aware of the facts. Similar notices with regard to appointment appear in every number of the *British Medical Journal*. But in England there has always been more regard for the liberty of the subject than in countries supposed to be more democratic.

The Influenza Epidemic

From sixty-six deaths in the last week of January the deaths from influenza increased steadily in the large towns of this country till the week ending March 27, when they reached 392. Since that date there has been a gradual falling off to the present figure of 306.

RIO DE JANEIRO

(From Our Regular Correspondent)

May 1, 1920.

Influenza

In the months of January and February there was a slight increase in the cases of influenza, most of which were mild, and therefore did not influence the death rate.

The severe quarantine measures taken by the board of health compelling steamships to remain in Rio de Janeiro Harbor, for ten or more days without being allowed to disembark passengers or unload, caused great disappointment among business men. The Royal Mail Steamship Company even threatened to suspend traffic between European and Brazilian ports. Prof. Azevedo Sodré wrote strongly against these obsolete measures. After discussion, Dr. Chagas agreed finally to change this quarantine prophylaxis to sanitary observation of passengers.

New Medical Journal

A new medical journal, *Folha Médica*, has been founded. Its editors are Profs. Aloysio de Castro, Bruno Lobo, Silva Santos, Ernani Pinto, Roquette Pinto and Francisco Lafayette, and Drs. Aben Athar and Octavio de Freitas, and it will be published bimonthly.

Newly Appointed Alienists for the Insane Asylum

Dr. Rocha Vaz, recently appointed professor in the Medical School, has been replaced as alienist of the asylum by Dr. Ernani Lopes. Dr. F. Esposel has taken the place of the late Dr. Sá Ferreira.

Brazilian Physicians for the League of Nations

Drs. Afranio Peixoto and Belisario Penna have been appointed Brazilian representatives on the section of international hygiene of the League of Nations.

Hospital for Venereal Diseases

The late Candido Gaffrée, a well known millionaire, has left \$100,000 for the foundation of a hospital for the treatment of venereal diseases. His heirs have decided to establish stations in different parts of the city for this purpose. They also intend to open an institute for the application of radium and later a laboratory for medical research along the

lines of the Rockefeller Institute. Dr. Gilberto Costa has been named to be director of the venereal hospital.

Paraguay Invites Brazilian Professor

The government of Paraguay asked Dr. Aloysio de Castro, director of the Medical School of Rio de Janeiro, to choose a competent professor to occupy the chair of physiology in the Faculty of Asuncion. He chose first Dr. Alvaro Osorio de Almeida, who could not accept the call, and then Drs. Mauricio de Medeiros, Chagas Leite and Roquette Pinto, but none of them accepted. The invitation is still open.

Examinations for the Chair of Chemistry in the Medical School

Drs. Nascimento Silva, Nascimento Bittencourt, Alfredo de Andrade and Pecegueiro do Amaral have been designated by the medical faculty to examine the thesis of Drs. Del Vecchio and Barros Terra, applicants to the position left vacant by the death of Dr. Diogenes Sampaio.

Portuguese Donation for the Centennial

The Portuguese colony of Rio de Janeiro has decided to build a large hospital which will be given to the city of Rio de Janeiro in September, 1922. The board of directors and the technical staff will be Brazilians of Portuguese descent.

Schistosoma Mansoni and Schistosomiasis Observed in Brazil

Dr. Adolpho Lutz has published an interesting paper on this subject, in which he discusses schistosomiasis in Africa and other continents, especially in America; recent observations in the north of Brazil; a description of the genus *Schistosoma* and differential characters of *Schistosoma mansoni*; characteristics of the eggs found in the feces; the embryo or miracidium inside the ripe egg; ecdysis and free life of the embryo or miracidium; penetrations of the miracidia in mollusks; development of sporocysts of the first and second generation; description of the cercariae; conditions under which the cercariae leave the snail; penetration of the cercariae; evolution of *Schistosoma* in mammalia; symptomatology of schistosomiasis; complications and secondary affections; pathologic anatomy; prognosis; therapeutics; prophylaxis, and the danger of bathing in stagnant waters. He concludes that schistosomiasis in Brazil is usually not severe, and that the proportion of unobserved cases is rather large.

Marriages

JOHN FRANCIS CORBY, Major, M. C., U. S. Army, to Miss Helen Horsman Wilcox, both of New York City, May 22.

HAL MCCLUNEY DAVISON, Atlanta, Ga., to Miss Alexivena Natasha Becklimesheff, at Vladivostok, Siberia, May 31.

WILLIAM TECUMSEH ELAM, St. Joseph, Mo., to Miss Eleanor Carlson of St. Louis, early in May.

ALLEN ROGERS BARROW, Newtonville, Mass., to Miss Mary Warren of Brookline, Mass., April 22.

ALBERT GRIFFITH MILLER to Miss Katherine E. Frutchey, both of Philadelphia, February 10.

JEFFREY NEESE ELDER, Hopewell, Va., to Miss Myrle Fagg of Christiansburg, Va., March 9.

JAMES NEWBIGIN WORCESTER to Miss Gertrude Fullerton, both of New York City, May 19.

SIMON STEIN LEOPOLD to Miss Loraine Livingston, both of Philadelphia, February 18.

DANIEL D. TALLEY, JR., to Miss Anne Hays Myers, both of Richmond, Va., April 29.

F. A. WHITE to Mrs. F. F. Brown of Wapanucka, Okla., at Durant, February 27.

Deaths

Stanton Abeles Friedberg ☉ Chicago; Rush Medical College, 1897; aged 44; died in the Presbyterian Hospital, May 27, following an operation for mastoiditis. He was assistant professor of laryngology and otology in his alma mater, and attending laryngologist to the Presbyterian and Durand hospitals; a member of the American Laryngological, Rhinological and Otolological Society, and secretary-treasurer of the Chicago Society of Medical History. During the war he served eighteen months at home and in France as major, M. C., U. S. Army, receiving his discharge April 29, 1919. He was well known for his work in bronchoscopy and for research on bacteria carriers.

James Adrian Goggans, Alexander City, Ala.; University of the City of New York, 1877; aged 66; a member of the Medical Association of the State of Alabama; a pioneer surgeon of Central Alabama; formerly president of the Tri-State Medical Society of Alabama, Georgia and Tennessee, and vice president of the Southern Surgical and Gynecological Association; health officer of Tallapoosa County since 1871; died at the home of his brother, April 25, from carcinoma of the cecum.

Henry Lawrence Orth, Harrisburg, Pa.; University of Pennsylvania, Philadelphia, 1866; aged 77; a member and once president of the Medical Society of the State of Pennsylvania; formerly local surgeon of the Pennsylvania, Northern Central and Pittsburgh and Lake Erie railroads; superintendent of the Pennsylvania State Lunatic Hospital, Harrisburg, for twenty-seven years; a medical cadet in the Civil War; died, May 18.

William Hadley Slacer, Buffalo; University of Buffalo, 1873; aged 75; for many years chief of the medical staff of the Sisters' Charity Hospital, and physician to the Edward Street Orphan Asylum; local surgeon of the Michigan Central Railroad, and medical director of the Protective Life Assurance Society of Buffalo; died, May 16, as the result of injuries received several months before in a street car accident.

Emil Anderson Lynwood ☉ Chicago; Dearborn Medical College, Chicago, 1907; aged 44; captain, M. C., U. S. Army, with service overseas and discharged June 30, 1919; a patient in the United States Public Health Service Hospital, Forty-Seventh Street and Drexel Boulevard, Chicago; died in that institution, May 27, from diabetes.

Max Carl Breuer ☉ Buffalo; University of Breslau, Germany, 1890; aged 55; gynecologist to the Memorial Hospital, and consulting gynecologist to the Deaconess Hospital, Buffalo; died in the latter institution, May 19, from septicemia due to a wound received while performing an operation.

Ellen Broadway Smith ☉ Salem, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; aged 54; while crossing the street to her office, May 13, was struck by an automobile, sustaining a fracture of the skull and other injuries from which she died a few minutes later.

James Henry Spencer, Tacoma, Wash.; University of Louisville, Ky., 1889; aged 58; for several years physician in the U. S. Indian Service at Ashland, Wis.; a specialist in diseases of the eye, ear, nose and throat; died at Santa Cruz, Calif., May 13, from chronic interstitial nephritis.

James Landon Taylor, Highland Park, Mich.; Medical College of Ohio, Cincinnati, 1872; aged 80; for many years a practitioner of Wheelersburg, Ohio; was struck by a street car while crossing a street in Detroit, May 3, and died in the Receiving Hospital, Detroit, May 6.

William Hampton Blythe ☉ Mt. Pleasant, Texas; Vanderbilt University, Nashville, 1886; aged 67; for more than twenty years secretary of the Titus County Medical Society and local surgeon of the Cotton Belt system; died, May 6, from senile debility.

Joseph Wiley McClendon, Dadeville, Ala.; Jefferson Medical College, 1888; aged 53; a member of the Medical Association of the State of Alabama; local surgeon of the Central of Georgia Railroad; died in Baltimore, May 13, from arteriosclerosis.

Mary Miller, Philadelphia; New York Medical College and Hospital for Women, Homeopathic, New York City, 1878; aged 82; died in the Home for Indigent Widows and

Single Women, Philadelphia, May 11, from cerebral hemorrhage.

Robert Steinfeld Willard, Ardmore, Okla.; University of Nashville, Tenn., 1899; aged 44; a member of the Oklahoma State Medical Association; formerly health officer of Ardmore; died in Lakeland, Fla., March 1, from influenza.

George Howard Cantwell, New York City; Jefferson Medical College, 1884; aged 62; for twelve years a surgeon for the Panama Steamship Company; died in Bellevue Hospital, May 19, from the effects of an overdose of morphin.

Joseph Davis Bennett, Safety Harbor, Fla.; St. Louis Medical College, 1867; aged 73; a Confederate Veteran; once vice president of the Florida Medical Association; died at Del Oro Grove, Safety Harbor, Fla., March 28.

William Ashburn Swearingen, Carothersville, Mo.; Barnes Medical College, St. Louis, 1900; aged 47; a member of the Missouri State Medical Association; also a druggist; died at Dawson Springs, Ky., May 4, from nephritis.

William Martin Johnson, Peckham, Okla.; University Medical College, Arkansas, Mo., 1890; aged 65; a member of the Oklahoma State Medical Association; died in Oklahoma City, February 13, after a surgical operation.

Albert Dell Swartz, Indianapolis; Indiana University, Bloomington and Indianapolis, 1908; aged 53; formerly superintendent of the Florence Crittenden Home; died in the Methodist Hospital, Indianapolis, May 17.

George D. Bradford ☉ Homer, N. Y.; University of Buffalo, 1875; aged 67; physician to the Cortland County and Homer Hospital; died in a hospital in Syracuse, N. Y., April 24, after a surgical operation.

Francesco Goglia, Elmira, N. Y.; University of Naples, Italy, 1902; aged 57; also a graduate in law; who was struck by an automobile, May 2; died from his injuries in St. Joseph's Hospital, Elmira, May 27.

Charles Baxter Wiseman, Henrietta, N. C.; College of Physicians and Surgeons, Baltimore, 1902; aged 51; a member of the Medical Society of the State of North Carolina; died, May 7.

Donald McPhail, Randolph, Va.; Medical College of Virginia, Richmond, 1878; aged 65; a member of the Medical Society of Virginia; died in a hospital in Richmond, March 11.

Corresta T. Canfield, Pittsburg, Kan.; Homeopathic Hospital College, Cleveland, 1872; aged 87; died at the home of her daughter in Pittsburg, May 1, following an attack of influenza.

Cassius Herschell Ice, Mannington, W. Va.; University of Maryland, Baltimore, 1891; a member of the West Virginia State Medical Association; died, March 21, from heart disease.

Herbert H. Gipson, Oklahoma City; Washington University, St. Louis, 1907; aged 40; a member of the Oklahoma State Medical Association; died, February 11, from influenza.

Silas T. Burch, Alex, Okla.; University of Tennessee, Nashville, 1884; St. Louis College of Physicians and Surgeons, 1898; aged 66; died, April 23, from acute indigestion.

Caroline Mary Smith, Milford, Conn.; New York Medical College and Hospital for Women, Homeopathic, New York City, 1895; aged 80; died, May 12, from heart disease.

George Albert Ross ☉ Fort Wayne, Ind.; Pulte Medical College, Cincinnati, 1879; aged 63; died in the Lutheran Hospital, Fort Wayne, May 13, from gallstone disease.

Theodore W. Helming, Indianapolis; Medical College of Indiana, Indianapolis, 1887; aged 55; a member of the Indiana State Medical Association; died, April 19.

Frank Edward Barrett, Wendell, Idaho; University of Kansas, Lawrence and Rosedale, 1912; aged 44; died at the home of his parents in Wendell, April 28.

John Franklin Hicks, Bristol, Tenn.; New Orleans School of Medicine, 1866; aged 91; for several terms a member of the Bristol city council; died, April 21.

John H. Barker, Bellevue, Ky.; Medical College of Ohio, Cincinnati, 1877; aged 67; a member of the Kentucky State Medical Association; died, April 20.

George F. E. Wilharm, Crafton, Pa. (license, Allegheny County, Pa., 1881); aged 67; a practitioner for forty years; died, May 11, from pneumonia.

R. H. Wilson, Sour Lake, Texas; Gate City Medical College, Texarkana, Texas, 1907; aged 61; died in a sanatorium in Houston, Texas, April 30.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

SYRUP LEPTINOL (FORMERLY SYRUP BALSAMEA)

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report on "Syrup Leptinol" (formerly "Syrup Balsamea"). The product is inadmissible to "New and Nonofficial Remedies," first, because the manufacturers fail to give the profession information regarding either the amount of the potent ingredient or the method of determining its identity and uniformity; second, because of the unwarranted recommendation for its use in such infectious diseases as pneumonia and epidemic influenza and for lack of satisfactory supporting evidence of its alleged therapeutic efficacy in other diseases and, third, because the recommendations for its use appearing on and in the trade package constitute an indirect advertisement to the public.

W. A. PUCKNER, Secretary.

Syrup Leptinol is sold by the Balsamea Co. of San Francisco. It was first introduced as Syrup Balsamea. In recent advertising, Syrup Leptinol is also referred to simply as "Leptinol."

According to the statements of the Balsamea Co. Syrup Leptinol is prepared from the root of a species of *Leptotaenia* (a plant belonging to the *parsnip* family) which grows in Nevada and which has heretofore not been used in medicine. The manufacturer states that the botanists who have been consulted have been unable to agree on the botanical classification of the plant. The dried root of this unclassified species of *Leptotaenia* is extracted with alcohol and from the extract so obtained the syrup is made, but no information has been furnished to show how the alcohol-soluble material is incorporated in the syrup. Further, the manufacturer has not announced tests whereby the identity and uniformity of the finished preparation may be determined.

A booklet contains the following:

"The species of *Leptotaenia* from which LEPTINOL is produced was first used in medicine by Dr. E. T. Krebs, who, after thorough laboratory investigation and clinical application over a period of several months, which resulted in the perfecting of LEPTINOL, prescribed the preparation for Influenza during the epidemic of that disease in 1918 with remarkably good results. Since this first use, LEPTINOL has been exhaustively tested by clinicians in private practice and in hospitals in the treatment of Pneumonia, Influenza, Bronchitis, etc., and has been universally endorsed."

In a circular letter it is asserted that the use of "Leptinol" during the "influenza epidemic" of 1918-1919 "demonstrated its almost specific action in respiratory affections"; that "during this epidemic it proved to be five times as efficacious

as any other treatment in pneumonia . . ."; and that "it is now as firmly fixed in the mind of many doctors for respiratory diseases as quinine is for malaria and the salicylates for rheumatism."

In the booklet it is further stated that the therapeutic action of the preparation is primarily that of a "stimulating expectorant" and secondarily as a "sedative expectorant"; that "its antiseptic action in the respiratory tract is prompt"; that it "is an effectual cardiac tonic where the tone of the heart muscle is impaired by fever"; that "in acute pulmonary conditions it effectively improves the respiratory action and allays cerebral irritation due to fever and toxins"; that it acts "as a vital stimulant and nerve sedative"; that "it stimulates the excretion of acid by the skin and in fever it has a strongly diaphoretic and antipyretic action without

depressing the circulation or the central nervous system"; that it is "mildly diuretic" and "slightly augments the biliary flow" and that "it increases the gastric and intestinal secretions and allays intestinal fermentation."

No evidence has been presented to the Council which shows that Syrup Leptinol has the actions ascribed to it. The reports of clinical trial¹ are little more than chance observations and lack all control.

The Council finds Syrup Leptinol (formerly Syrup Balsamea) inadmissible to New and Non-official Remedies because: (1) the information in regard to composition does not state the amount of potent ingredient, nor permit the determination of its identity and uniformity; (2) the recommendation for its use in such infectious diseases as pneumonia and epidemic influenza is unwarranted and its claimed therapeutic efficacy in other diseases is without satisfactory supporting evidence; and (3) the recommendations for its use which appear on the label and the circular wrapped with the trade package constitute an indirect advertisement to the public.

The Council accepts the explanation of the manufacturer that he has been unable to obtain a satisfactory classification of the plant from which Syrup Leptinol is made. It would be undesirable to exclude from therapeutic use a valuable drug simply because its botanical character has not been determined or because an exhaustive chemical examination had so far not been made. However, in

the absence of such information the manufacturer should give full information with regard to the preparation or standardization of his remedy and the therapeutic claims made for it should be accompanied by indisputable, thoroughly controlled clinical evidence. In the case of Syrup Leptinol, there is no satisfactory evidence available showing that the preparation has any value in the treatment of epidemic influenza, pneumonia, whooping cough, etc. While it is probable that a balsamic syrup, such as Syrup Leptinol, has palliative properties in coughs, such action does not at all justify the claim that it is useful in the contagious diseases for which it is proposed.

1. Among these reports is one from a mining hospital. The Council discusses this in its original report (a copy of which may be had on application) but the discussion is omitted here for lack of space.

The Council cannot recognize a syrup presenting an unknown plant in uncertain proportions which is recommended in a variety of dangerous contagious diseases in which it ultimately may be harmful, even though in early stages of these diseases, it may serve to allay some of the milder symptoms.

Concerning the composition of the plant from which Syrup Leptinol is prepared, the Balsamea Company states that it contains "Alkaloids, acids, glucosides, volatile and fixed oils, gum and resins." This information is valueless since no information is given concerning the character, amounts or pharmacologic action of the ingredients. Further, it is unreliable as far as the presence of alkaloids is concerned since the A. M. A. Chemical Laboratory has been unable to find any alkaloids in the specimen of the crude drug furnished by the manufacturers.

In accordance with its regular procedure, the Council submitted the preceding statement to the manufacturer.

In reply the Balsamea Company stated that it is more than ever of the belief that Syrup Leptinol is deserving of recognition by the Council, basing this opinion on further clinical experience with it in the treatment of influenza.

The manufacturer stated that the use of the words "Leptinol" and "Syrup Leptinol" interchangeably was due to an oversight and promised to limit the use of the word "Leptinol" to an alcoholic extract of the plant.

Concerning the method of preparation of this alcoholic extract and the amount used in the preparation of Syrup Leptinol the Balsamea Company replied as follows:

"The alcoholic extract of the Leptotaenia, which we have termed 'Leptinol' is a preparation of definite and uniform strength, as determined by two methods: (a) the gravity test using the U. S. Hydrometer Scale for spirits, by which Leptinol registers 52 degrees at 60 degrees F., and (b) by gentle evaporation of the alcohol content and the measuring of the active constituents, which measures twenty-five per cent. by weight.

"The alcoholic extract 'Leptinol' is glycerinated in a machine, using one part of the alcoholic concentration to four parts of glycerin. This is then added to eleven parts of a heavy syrup, containing $7\frac{1}{2}$ pounds of sugar to the gallon of syrup, and thoroughly mixed in an agitating machine. Leptinol is the sole active ingredient of Syrup Leptinol. Syrup Leptinol is a preparation of uniform strength. It is far more uniform in strength than most of the syrups of the U. S. P. made from fluid extracts which are made from crude drugs which are not uniform in strength."

This claim cannot be allowed as meeting the conflict with Rule 1. It is well known that plants vary in their composition at different times of the year; under different conditions of cultivation and growth; and under varying other conditions; hence the claim that alcoholic extracts of equal specific gravity insure uniformity of composition in active principles must be considered entirely illogical, especially since the exact nature of the active principles, if any be present, is unknown. If these are known their nature should be stated and tests for their identity be given. If they are unknown it is manifestly misleading to state that the preparation is of uniform strength.

It is evident that the Council cannot approve of the use of a preparation of unknown composition without satisfactory evidence of its value, especially when it is recommended in a variety of serious infectious diseases such as influenza and pneumonia. The mere fact that a small number of patients who have received the drug recover is no evidence of its curative value, and until carefully controlled clinical tests of the preparation are made, it is not entitled to the consideration of physicians.

Every Physician a Health Officer.—Hasty conditions of work, failure to employ laboratory means of diagnosis or to utilize available consultation facilities (especially in tuberculosis), and lack of training of medical practitioners in preventive medicine, are among the obstacles to further control of disease. There will not be complete success until means are discovered for enlisting every medical practitioner as a medical officer of health in the circle of his private or public practice, and for securing his services not only in the early and prompt detection of disease, but also in the systematic supervision during health of the families under his care, and in advising them as to habits or methods of life which are inimical to health.—Arthur Newsholme, *Commonwealth*, November-December, 1919.

THE DISCOVERY OF THE ANESTHETIC PROPERTIES OF COCAIN

To the Editor:—While preparing the report of the Committee on Local Anesthesia at the request of the Committee on Therapeutic Research of the American Medical Association and the Section on Laryngology, Otology and Rhinology for the New Orleans meeting, I had an interview with Dr. Carl Koller, who gave me some interesting history relative to the discovery of the anesthetic properties of cocaine. I asked him to write out the facts. This he has done; and as a historical contribution to this most important therapeutic advance, I feel that it merits publicity.

EMIL MAYER, M.D., New York.

Chairman, Committee on Local Anesthesia.

Up to the year 1884, the only method of local anesthesia known was the Richardson ether spray, which acted by freezing, and which was used for opening abscesses and similar operations of short duration. The immediate cause for my approaching the question of local anesthesia was the unsuitability of general narcosis in the case of eye operations. For not only is the cooperation of the patient in these greatly desirable, but the sequels of general narcosis—vomiting and retching—are frequently such as to constitute grave danger to the operated eye; this was especially the case at the time mentioned, when narcosis was not so skilfully administered as it is now. My teacher Arlt in his operative courses used to dwell on this subject. Eye operations used to be performed without any anesthetic whatever. Searching for a local anesthetic, I had for about a year tried various substances for their anesthetic effect on the eye, performing many experiments on animals. Thus I tried chloral, bromid and morphin. Having no success, I had for the time given up these experiments, which, however, prepared me to grasp a local anesthetic whenever I should encounter one.

About that time my friend Sigmund Freud, the same man who later achieved fame as the author of psychoanalysis, asked me to help him with experiments on the physiologic effects of cocaine, when taken internally. We used to take some of the drug, of which only a very small quantity was in existence, and make various tests as to its effects on muscular strength, fatigue and the like. I noticed the peculiar benumbing effect on the tongue, a fact which was well known and which was noted in the textbooks on pharmacology and toxicology (Niemann, who isolated the alkaloid from the coca leaves mentioned it as far back as 1860), but the evident and important consequences of which had not been drawn. Like a flash it occurred to me that this was the local anesthetic for which I had been looking. I went at once to Stricker's laboratory of experimental pathology and tried it first on the eye of a frog, then on a guinea-pig, afterward on myself and then on patients. It is not correct, as said at the time, that I had discovered this important fact by accident, a drop coming by chance in my eye. If such had happened I would not have known that the eye was bereft of sensibility. I made the first publication relative to this subject, Sept. 15, 1884, at the meeting of the German Ophthalmological Society at Heidelberg; I was not present at this meeting; Dr. Brettauer of Trieste read a short communication for me and showed the experiments. Later I read a more elaborate paper before the Society of Physicians at Vienna. From the beginning I was aware that the new anesthetic had a wide application in other branches of medicine and surgery. Owing to my direct suggestion it was

tried in the field of laryngology and rhinology by Jellinek, who at that time was assistant to Schroetter in Vienna. The knowledge of the new remedy spread quickly, and before long it was in general use in all the specialties and in general surgery.

CARL KOLLER, M.D., New York.

"CHRISTIAN SCIENCE' AND SLOPPY THINKING"

To the Editor:—The editorial in THE JOURNAL of May 22, headed "'Christian Science' and Sloppy Thinking," was quite characteristic of the attitude of those who believe that material medicine is the only hope of mankind for the healing of disease. The claim that material medicine is a science, and the practice of it is scientific, brings a smile because all people are not credulous. The majority of people are quite aware of the fallibility of medical diagnosis of disease and the consequent failure of medicine to heal. Many people have been victims of mistaken diagnosis and are awake to the effort being made to make unlawful the treatment of all disease, except by doctors of medicine. They are also awake to the fact that an attempt to confer such a monopoly on that method of treatment is forbidden by our Constitution.

A prominent clergyman, managing editor of a well-known religious publication, was frank enough to say: "The reason why Christian Science is in the world is because the evangelical churches failed to preach and practice Christian healing as taught and demanded by Christ Jesus." An additional reason why Christian Science is in the world today, reinstating primitive Christianity and its correlative, the lost element of healing, is because of the failure of materia medica to be the healer of disease that it claims to be. The greater number of people in the world who call themselves Christian Scientists are so because of the failure of medicine to heal them. The writer is one of them.

The assertion that if the father in Newark, New Jersey, had called a physician his daughter would not have died of diphtheria, is a marked exhibition of medical assumption. The statistics supplied by the health departments successfully dispute this claim, for by far the greatest number of those who died of that disease had the care of a physician. A news item in the New York *World*, June 12, 1916, said: "A special inquiry by the Department of Health shows that the discovery and widespread use of diphtheria antitoxin since 1907, has not materially reduced either the prevalence of the disease or the percentage of deaths, particularly the last five years."

The world objects to polygamy because it views it as immoral, and the attempt to draw a parallel between it and Christian healing, is farfetched and is a direct affront to a large body of law abiding citizens. To draw such a parallel surprisingly rejects the healing work of the Master, who said (John 5:36): "The same works that I do, bear witness of me, that the Father hath sent me." The healing work of the Great Physician was scoffed at and rejected as the repetition of that work is being rejected today, and yet Jesus taught plainly (John 14:12), "He that believeth on me, the works that I do shall he do also." There is today no greater safeguard to the health and morals of the people than that which is based on the teaching of Christian Science and which is manifested through the practice of it, and this in the face of all statements to the contrary.

The admonition of "a Pharisee, named Gamaliel, a doctor of the law," is as much to the point now as it was the day it was uttered (Acts 5:38-39) "And now I say unto you, Refrain from these men, and let them alone: for if this counsel or this work be of men it will come to nought: But

if it be of God, ye cannot overthrow it; lest haply ye be found even to fight against God."

Objection was made to "a religious cult with money and well organized publicity machinery behind it." What words, omitting the word "religious" could more accurately define and describe the status and activities of the allopath medical organization than the ones quoted? Why, then, the self-righteousness of the medical men? If the word "cult" is intended to refer to Christian Science, then it is proper to explain that the reason it is organized and active is because it is compelled to be so in order to defend the Constitutional right of its followers.

I shall appreciate the courtesy of your printing this letter, without comment, in the next issue of THE JOURNAL.

LEE WHITE, Chicago.

Christian Science Committee on Publication
for the State of Illinois.

[COMMENT.—Mr. White's letter justifies the caption of the editorial to which he objects; his arguments prove that the indictment "sloppy thinking" was amply justified.

Mr. White says: "The assertion that if the father in Newark, N. J., had called a physician, his daughter would not have died of diphtheria, is a marked exhibition of medical assumption." It certainly would be! But no such assertion was made. Where the father erred was in not giving the child the benefit of the best help that modern knowledge has to offer. Had the 9-year-old girl been buried beneath a load of bricks, even Mr. White would have suggested, we believe, that before giving the injured child "Christian Science" treatment—"absent" or "present"—the bricks should be removed. What Mr. White fails to realize is that a Klebs-Loeffler bacillus is just as material an object as a brick. It does material damage, it is true, not by its material weight, but by the equally material toxins it produces. It would be just as irrational to read Mrs. Eddy's "Scientific Statement of Being" to a child while bricks were permitted to remain on her mangled body as it is to read the same thing to a child whose system is being overwhelmed with toxins that can, at a certain stage at least, be neutralized. It is readily admitted that removing the bricks might not save the child's life, but such action would be the first thing to do.

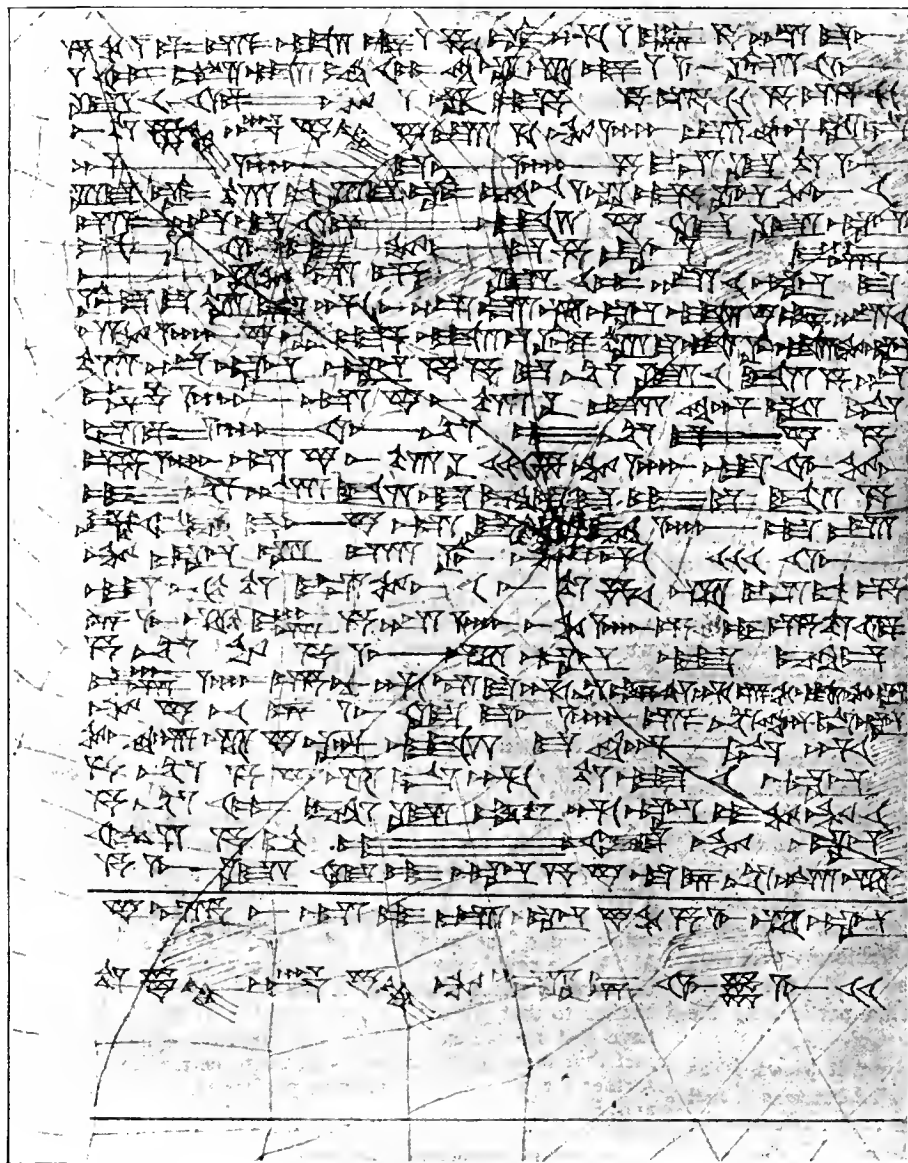

Mr. White holds that the medical treatment of diphtheria is unsuccessful because "by far the greatest number of those who died of that disease had the care of a physician." More sloppy thinking! With equal accuracy—and sophistry—it could be said that practically all who die of diphtheria die while under "the care of a physician." By the same logic Mr. White could prove that a bed is the most dangerous place on earth because most people die in it. His argument is similar to that put out by other drugless cults who claim to have lost no patients during the influenza epidemic. The fact that these gentry cannot sign death certificates, and the further fact that even people who profess to rely on "Science and Health" usually call in a physician when their illness reaches a critical stage, are utterly ignored.

Mr. White objects to THE JOURNAL'S parallelism between the religious belief of the Mormons in polygamy and the religious belief of the Christian Scientists in the immateriality of disease. He says that the world objects to polygamy because it views it as immoral. True; and if the rank and file of the people were as well grounded in scientific knowledge and methods of thought as they should be, the world would view some of the bizarre conceptions of the Christian Scientists as immoral.

Finally, why does Mr. White ask us to print his letter "without comment"? Is it because he realizes the weakness of his cause, or is it, perchance, another exhibition of the growing intolerance of criticism of the organization he represents? It may or may not be true that this cult can exercise sufficient influence to close the pages of newspapers against criticism of their organization, and it may or may not be influential enough to bring about the discharge of newspaper men who happen to incur their displeasure. It does not, however, control the medical press.—Ed.]

A UNIQUE BIRTHDAY TESTIMONIAL TO DR. WELCH

This facsimile reproduction is a message in cuneiform characters to Dr. William H. Welch on his seventieth birthday. The author is Paul Haupt, who, since 1883, has been Spence professor of Semitic languages and director of the Oriental Seminary of Johns Hopkins University. The original was written on antique, clay-colored paper, the third sheet bearing a key to pronunciation, and the fourth sheet a translation into English.

CUNEIFORM WRITING

The peculiar characters, called cuneiform writing, were first used in Mesopotamia, it is believed, about 4000 B. C. The Assyro-Babylonian, which grew from this, contained over 700 characters, partly alphabetic and partly syllabic. It is read from left to right. The characters were usually cut with a stylus in soft clay or stone, this governing their shape. The arrow heads are presumably due to the first impression of the point in the clay. Especially interesting to physicians is the Code of Hammurabi, who reigned in Babylon about 2250 B. C. Here occur such words as *asu*, physician; *asakku*, disease, and *marsu*, sickness. This code defined the legal status of physician and contained the first fee bill.

TRANSLATION

Message of Paul, the Son of Haupt, to the great Physician.
William Henry, the son of Welch:
A hearty, hearty greeting to my lord!
On the eighth day of the fourth month when thou wast born
70 years ago,

May the great gods decree length of days,
Health of mind and body for my lord.
May they let thee eat the plant of life
Whose name is A gray-haired man became young;
May they let thee bathe in the fountain
Which removes all uncleanness from thy body.
May they guard the life of my lord, and keep thee whole!
May thy heart ever be of good cheer!
The gates of the city in which thou wast born
Lift up their head;
The people of the city in which thou hast lived for 36 years

Look up to thee and rejoice.
Thou art a great monument of the Monumental City,
The founder of the new Temple of Health,
A great helper in the great war.
Thou has brought to America
The wisdom of the physicians in the countries across
the sea.
Mighty kings have bestowed glorious insignia on thee,
Great seats of learning have honored thee,
Numerous bands of scholars have chosen thee as their leader,
They listen to thy wise counsel,
They love thee like a father.
We shall not look upon thy like again.
Written in the city of Ithaca in the land of America
On the seventh day of the fourth month in the year of our
Lord 1920.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

ALABAMA: Montgomery, July 13. Chairman, Dr. S. W. Welch, Montgomery.

ARIZONA: Phoenix, July 6-7. Sec., Dr. Ancil Martin, 207 Goodrich Bldg., Phoenix.

CALIFORNIA: San Francisco, June 28-July 1. Sec., Dr. Chas. B. Pinkham, 135 Stockton St., San Francisco.

COLORADO: Denver, July 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

CONNECTICUT: Hartford, July 6-7. Sec., Regular Board, Dr. Robert L. Rowley, 49 Pearl St., Hartford.

CONNECTICUT: New Haven, July 13. Sec. Eclectic Board, Dr. James Edwin Hair, 730 State St., Bridgeport. Sec. Homeo. Board, Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

DELAWARE: Wilmington, June 15-17. Pres. Medical Council, Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

DISTRICT OF COLUMBIA: Washington, July 13-15. Sec., Dr. Edgar P. Copeland, The Rockingham, Washington.

FLORIDA: Eclectic Board, Jacksonville, June 18-19. Sec., Dr. G. A. Munch, 1306 Franklin St., Tampa.

FLORIDA: Regular Board, Jacksonville, June 14-15. Sec., Dr. Wm. M. Rowlett, Citizens Bank Bldg., Tampa.

GEORGIA: Atlanta, June 9-11. Sec., Dr. C. T. Nolan, Marietta.

ILLINOIS: Chicago, June 14-17. Director, Mr. Francis W. Shepardson, Springfield.

IOWA: Iowa City, June 16-18. Sec., Dr. Guilford H. Sumner, Capitol Bldg., Des Moines.

KANSAS: Topeka, June 15-16. Sec., Dr. H. A. Dykes, Lebanon.

LOUISIANA: New Orleans, June 10-12. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.

MAINE: Portland, July 6-7. Sec., Dr. Frank W. Searle, 140 Pine St., Portland.

MARYLAND: Baltimore, June 15. Sec., Dr. J. McP. Scott, 137 W. Washington St., Hagerstown.

MICHIGAN: Ann Arbor, June 8-10. Sec., Dr. B. D. Harrison, 504 Washington Arcade, Detroit.

MISSOURI: St. Louis, June 14-16. Sec., Dr. Geo. H. Jones, State House, Jefferson City.

NEBRASKA: Lincoln, June 9-11. Sec., Department of Public Welfare, Mr. H. H. Antles, Lincoln.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. Alexander MacAlister, State House, Trenton.

NEW MEXICO: Santa Fe, July 12-13. Sec., Dr. R. E. McBride, Las Cruces.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. Geo. M. Williamson, 860 Belmont Ave., Grand Forks.

OHIO: Columbus, June 8-11. Sec., Dr. H. M. Platter, State House, Columbus.

OKLAHOMA: Oklahoma City, July 13-14. Sec., Dr. James M. Byrum, Mammoth Bldg., Shawnee.

OREGON: Portland, July 6. Sec., Dr. Urling C. Coe, 1208 Stevens Bldg., Portland.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Sec., Dr. Thos. E. Finnegan, State Capitol, Harrisburg.

RHODE ISLAND: Providence, July 1-2. Sec., Dr. Byron U. Richards, State House, Providence.

SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Boozer, 1806 Hampton St., Columbia.

SOUTH DAKOTA: Deadwood, July 13. Sec., Dr. Park B. Jenkins, Waubay.

TENNESSEE: Memphis, Nashville and Knoxville, June 11-12. Sec., Dr. A. B. DeLoach, 1001 Exchange Bldg., Memphis.

TEXAS: Galveston, June 22-24. Sec., Dr. Thos. J. Crowe, Trust Bldg., Dallas.

UTAH: Salt Lake City, July 5-6. Sec., Dr. G. F. Harding, 405 Templeton Bldg., Salt Lake City.

VERMONT: Burlington, June 29-July 1. Sec., Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 22-25. Sec., Dr. J. W. Preston, McBain Bldg., Roanoke.

WASHINGTON: Seattle, July 6-8. Sec., Dr. Wm. M. O'Shea, 305 Old National Bank Bldg., Spokane.

WEST VIRGINIA: Charleston, July 13. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

WISCONSIN: Milwaukee, June 29-July 1. Sec., Dr. John M. Dodd, 220 E. Second St., Ashland.

WYOMING: Cheyenne, June 7-9. Sec., Dr. J. D. Shingle, Cheyenne.

Connecticut March Examination

Dr. Robert L. Rowley, secretary of the Connecticut Medical Examining Board, reports the written examination held at Hartford, March 9-10, 1920. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 28 candidates examined, 21 passed and 7 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Yale University	(1918) 90.6,	(1919)	88.3
Bennett Medical College	(1914)		81.9
Bowdoin Medical School	(1919)		86.2
Johns Hopkins University	(1916) 81.9,	(1919)	85.6
University of Maryland	(1918)		76.1
Harvard University	(1902) 79.4, (1903) 84.9,	(1919)	87.9
Tufts College Medical School	(1919)		77.5
Albany Medical College	(1898) 75.2,	(1917)	85.4
Columbia University	(1904) 86.1, (1918) 89.6,	(1919)	80.7
Fordham University	(1917) 79,	(1918)	77.3

Jefferson Medical College	(1915) 84.6	(1919)	75
Vanderbilt University	(1915)		78

FAILED

Bennett Medical College	(1914)	66.8
Chicago College of Medicine and Surgery	(1914)	66.3
Boston University	(1919)	69.9
Tufts College Medical School	(1919)	71.8
Woman's Medical College of Pennsylvania	(1915)	74
Meharry Medical College	(1913)	69
Medical College of Virginia	(1917)	66.4

Massachusetts March Examination

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, written and practical examination held at Boston, March 9-11, 1920. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 29 candidates examined, 20 passed and 9, including 1 osteopath, failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Georgetown University	(1910)		75.2
University of Georgia	(1913)		83.2
Chicago Hospital College of Medicine	(1919)		76.4
Bowdoin Medical School	(1915)		75
Harvard University	(1914) 82.6, 86.2, (1918) 84.6, (1919) 83.7, (1920) 79.3, 82.2, 82.5		
Tufts College Medical School	(1914) 79, (1917) 77.1, (1919)		78.5
St. Louis University	(1916)		82.7
Washington University	(1910)		85.7
Columbia University	(1901)		77.4
University of Vermont	(1915)		87.1
Medical College of Virginia	(1917)		78.6
University of Toronto	(1913)		80

FAILED

Baltimore Medical College	(1902)	67.1
Middlesex College of Med. and Surg.	(1919) 67.1, 70.6, 71.9, 73.2, (1920) 71.4	
Montreal School of Med. and Surg.	(1901) 64.6, (1919)	69.5

Rhode Island January Examination

Dr. Byron U. Richards, secretary of the Rhode Island State Board of Health, reports the written and practical examination held at Providence, Jan. 8-9, 1920. The examination covered 7 subjects and included 70 questions. An average of 80 per cent. was required to pass. Two candidates were examined and passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
University of Maryland	(1917)		88.5
Vanderbilt University	(1912)		88.7

Book Notices

PASTEUR: THE HISTORY OF A MIND. By Emile Duclaux, Professor at the Sorbonne. Translated by Erwin F. Smith and Florence Hedges, Pathologists of the U. S. Department of Agriculture. Paper. Price, \$5, net. Pp. 363, with illustrations. Philadelphia: W. B. Saunders Company, 1920.

Emile Duclaux, at the age of 19, entered the normal school in Paris, and came under the teachings of Louis Pasteur, under whose influence he remained until the death of the latter. "If Pasteur be an incomparable genius," says Dr. Erwin Smith, "Duclaux, at least, is his Boswell; but he is more than a mere Boswell, tagging around after a great man. He is, himself, a great man."

Duclaux's book, which is now presented in English for the first time, is more than a biography. There already exist excellent biographies of Pasteur; it is doubtful if biographic literature anywhere surpasses the life of Pasteur by his nephew, Paul Valery Radot. The present work is rather the history of Pasteur's influence on the development of the science of bacteriology and immunity. "I have desired, in the ensemble, as well as in the particulars," says Duclaux, "to give a genesis of his discoveries, believing that he has nothing to lose by this analysis, and that we have to gain." The book explains the origin of Pasteur's discoveries; their gradual development; the effect of discoveries made by others on Pasteur's work; famous controversies which arose on theoretical questions, etc. It is enlivened by scraps of con-

versation and with quotations from Pasteur's writings. It is illustrated with excellent reproductions of various photographs of Pasteur, and has an interesting appendix of brief biographic notices relative to various persons mentioned in the book.

As explained in the introduction, which includes an excellent brief biography of Duclaux, Dr. Erwin Smith began the translation, but eventually about two thirds of the translation from the French was made by Miss Florence Hedges. The whole was then worked over into its present English shape. This fact is mentioned, because the translation bears the marks of considerable unevenness. As pointed out by Tytler, in his famous Essay on the Principles of Translation, it is necessary, in order to produce an excellent piece of work, that the translator have equal facility with the two languages with which he works. That this facility was not always utilized is apparent from many sentences which appear in the latter part of the translation that are more French in their construction than English. Some examples follow:

Such being the case, what one has the right to ask is why these ideas did not attract the attention of contemporaries to a greater extent.

To make this idea acceptable to the illustrious practitioners, his colleagues in the Academy of Medicine, that they were responsible for the accidents which occurred to their patients, and that when there was a case of death by purulent infection in their service, or even merely a case of operative fever it was their fault, was a task that Pasteur had not ventured to assume, and yet one which he accomplished; because the new was certain to destroy the old, because it was only necessary to leave to itself the idea lodged in this Note in order to see it invade and overthrow everything.

However, these considerations will not weigh greatly against this book with any interested in the life of the great master, and in an appreciation of what his accomplishments have done for medical science. Duclaux's book presents these facts intimately and from the scientific point of view.

THE HYSTERIA OF LADY MACBETH. By Isador H. Coriat, M.D. Boards. Price, \$1.25. Pp. 94. New York: Moffat, Yard & Co., 1912.

According to the author, Lady Macbeth is a typical case of hysteria. "She is not a criminal type or an ambitious woman, but the victim of a pathological mental dissociation, arising upon an unstable, day-dreaming basis, and is due [sic] to the emotional shock of her past experiences." It has become quite the thing with the Freudians to take the beautiful imaginary conceptions of the great artists, writers and dramatists and psychanalyze them into expressions of the libido; this Freud himself has done for Leonardo Da Vinci, Ernest Jones for Hamlet, and Mordell for virtually all of the great poets and writers. Hamlet, we are informed, is a case of the Oedipus complex, and now, Lady Macbeth, because of her somnambulism, is transferred to the group of neurotics. The analyses are invariably clever, but sometimes rather banal. We are informed, for example, that in the words "Out damned spot! Out I say," the mechanism is that of an unconscious and automatic outburst. This is the very apotheosis of erudition. When Shakespeare's doctor later states of Lady Macbeth, "This disease is beyond my practice," he expresses, says Coriat, the doubt of the medical profession toward these psychoneurotic symptoms until the advent of modern psychopathology. It would seem that we must add to the many encomiums already conferred on the world's greatest dramatist the highest achievement of all: He was the first great Freudian!

THE NATURAL HISTORY OF THE CHILD. A Book for All Sorts and Conditions of Men, Women and Children. By Dr. Courtney Dunn. Cloth. Price, \$2 net. Pp., 316. New York: John Lane Company, 1920.

Strictly speaking, this is not a medical book, but rather an anthology of childhood collected from ancient and rare books, obscure pamphlets and papers. The material has been selected with excellent taste and with an intimate knowledge of the child. There are fourteen chapters, and they cover every phase of the child's life. Numerous quotations of a poetic and humorous character, and much of the folk lore and superstition attached to childhood are included. The book will be of interest to every one who is interested in or loves children—and who will admit that he is not?

Medicolegal

Definition of "Accident"—Rupture of Aorta

(*E. Baggot Co. v. Industrial Commission et al. (Ill.)*, 125 N. E. R. 254)

The Supreme Court of Illinois says that the word "accident" is not a technical legal term with a clearly defined meaning, and no legal definition has ever been given which has been found both exact and comprehensive as applied to all circumstances. Anything that happens without design is commonly called an "accident," and, at least in the popular acceptance of the word, any event which is unforeseen and not expected by the person to whom it happens is included in the term. The words "accident" and "accidental injury," as used in the workmen's compensation act of Illinois, were meant to include every injury suffered in the course of employment for which there was an existing right of action at the time the act was passed; also to extend the liability of the employer to make compensation for injuries for which he was not previously liable and to limit such compensation. If an injury can be traced to a definite time, place and cause, and the injury occurs in the course of the employment, the injury is accidental within the meaning of the act, and the obligation to provide and pay compensation arises.

In this case a part of the employee's work consisted in turning one handle of a windlass in a hand derrick used in raising material to an upper story of a building, his last load weighing between 250 and 300 pounds. Nothing unusual happened while the work of lifting this last load was in progress. The work was heavy, but it was the same kind of work that the two men engaged in it had been doing for a couple of days. But after this load was landed this employee was seen to be spitting blood. About twelve days later he died. A necropsy disclosed a large longitudinal tear and several smaller transverse tears in the walls of the aorta. The court thinks that all the characteristics of an accident were present. The occurrence was sudden, unexpected, and undesigned by the workman. The circumstances were clearly such that the industrial commission was justified in finding that the hemorrhage was due to blood pressure intensified by vigorous muscular exertion. Relating the hemorrhage to physical exertion, rupture of the aorta by force from within was as distinctly traumatic as if the canal had been severed by violent application of a sharp instrument from without.

Druggists Changing Directions—Physician as Unfriendly Witness

(*Marx v. Schultz et al. (Mich.)*, 175 N. W. R. 182)

The Supreme Court of Michigan, in reversing a judgment directed for the defendants and in ordering a new trial, says that the action was brought to recover damages suffered by the plaintiff on account of the death of his wife, alleged to have been caused through the negligence of the defendants, or of some of them. A physician, who was treating Mrs. Marx, had written a prescription for Fowler's solution of arsenic, directing the taking of three drops of it in water after meals, three times daily, which prescription had been sent to a drug store, the property of some of the defendants. There it had been filled, and the medicine delivered at the Marx home. The bottle bore an ordinary label, on which was the name of the physician, followed by the directions: "Teaspoonful in water after meals three times daily, 11-30-15." There was nothing to indicate the poisonous nature of the liquid. One teaspoonful was taken. The death of the patient occurred between nine and ten weeks later.

The physician's diagnosis corresponded to that of the county physician, who stated that the necropsy which he made was the basis for his opinion that she had died of chronic Bright's disease of from one to ten years' standing.

To a physician of twenty-five years' practice, who was a graduate of the University of Michigan and who stated that he had made a study of the effect of arsenic on the human body, was submitted a hypothetic question, which recited the

giving of the prescription, Nov. 30, 1915, for a skin rash, with directions to take three drops after each meal, which directions were by mistake changed at the defendants' drug store to read "one teaspoonful after meals"; that one teaspoonful was given to Mrs. Marx, according to those directions, and immediately thereafter she appeared to be in great pain, suffered inward convulsions, threw herself from one side to the other of the bed, and continually tried to vomit; that her whole body became greatly swollen, and her mouth and tongue so increased in size that she could hardly talk; that after Nov. 30, 1915, large ulcers came in her mouth and nose, her eyes were swollen, and liquid appeared therein, her appetite was poor, and she complained at times of pains about her heart and an irritable condition of her bowels, the movement of which was frequent, the substance passed being bloody and yellow; that she was delirious off and on from the time she received the overdose, and the general conditions named continued down to the time of her death, Feb. 7, 1916.

The witness, in answer to the question whether, in his opinion, such conditions would be caused by the overdose of Fowler's solution of arsenic which Mrs. Marx received, and would the overdose be the proximate cause of her death, answered: "Those symptoms are caused by an excessive dose of arsenic and probably would result in her death." The court is of the opinion that this testimony was sufficient to warrant the drawing of an inference favorable to the plaintiff sufficient to present the disputed question of fact—which should have been presented to the jury—as to the cause of the death of the plaintiff's wife. As to whether the testimony of the defendant's witnesses outweighed that of the plaintiff was a question for the jury to determine in the first instance.

Some question was also made by the plaintiff's counsel of the undue limitation by the trial court of the examination of the attending physician, who wrote the prescription, whom the plaintiff was practically required to call. An attempt was made to show certain incidents between the plaintiff and the physician, in order to make it appear that the physician had become adverse and unfriendly to the plaintiff's cause. The court is of the opinion that the judge should have been more liberal in allowing a showing of this character to be made, in view of the fact that the physician, being the attending physician, it was almost obligatory on the plaintiff's counsel to put him on the stand in order to make out his case.

Unlawful Practice of Medicine

(*Black v. State (Texas)*, 216 S. W. R. 181)

The Court of Criminal Appeals of Texas, in affirming a judgment of conviction of defendant Black of unlawfully practicing medicine, for which he was fined \$250 and sentenced to one day in jail, says that it was entirely undisputed that he had and maintained offices where he treated any and all persons who might apply to him for various and sundry disorders and diseases, for compensation; and that he had not registered with the district clerk of the county, as required by the provisions of Chapter 6, Title 12, of Vernon's Penal Code. That act, passed by the legislature in 1907, makes it unlawful for any one to practice medicine on human beings in Texas, without registering with the district clerk in the manner and form provided by said act. By the terms of Article 755 of said chapter, what is meant by "practicing medicine," within the proscription of said statute, is defined. Subdivision 2 of that article is: "(2) Or who shall treat, or offer to treat, any disease or disorder, mental or physical, or any physical deformity or injury, by any system or method or to effect cures thereof, and charge therefor, directly or indirectly, money or other compensation." This act has been held constitutional both by this court and by the Supreme Court of the United States. It has been held to apply to a masseur; also to an osteopath; also to one who claimed to cure by means of laying on of hands and prayer—and this wholly regardless of whether such persons claimed to be physicians and practitioners of medicine or not.

AMERICAN SOCIETY FOR CLINICAL INVESTIGATION

Annual Meeting, held in Atlantic City, N. J., May 3, 1920

The Senior Councilor, DR. ERNEST E. IRONS, Chicago, in the Chair

The Mouth as an Environment for Bacterial Growth

DR. ARTHUR L. BLOOMFIELD, Baltimore: The following organisms were introduced into the various parts of the upper air passages: *Sarcina lutea*, *B. coli*, *Staphylococcus albus*, *B. influenzae*, Friedländer bacillus and *Streptococcus hemolyticus*. A loopful of twenty-four hour growth on solid medium was placed on the tongue and the nasal septum, or introduced into a tonsil crypt, and cultures were made at various intervals to determine the rate of disappearance. The general result of these experiments was that the bacteria disappeared rapidly, as a rule in less than twenty-four hours. In no case was disease produced. The explanation for the rapid disappearance of the organisms was found to be the mechanical flushing action of the mouth secretions, in some cases assisted by the destructive effect of the saliva. The free surfaces of the normal mucous membranes of the upper air passages do not furnish an environment in which foreign organisms can colonize, and special circumstances are required before they take hold locally and produce disease.

DISCUSSION

DR. ALFRED F. HESS, New York: Some years ago I attempted to ascertain whether bacteria are carried from mouth to mouth in children of a hospital ward. In order to determine this I swabbed the throats of several children with fresh cultures of *Bacillus prodigiosus*, with the object of ascertaining whether this pigmented bacillus would be carried to the mouths of the other children. Although large amounts were used on the tongue and on the cheeks, it was found that it disappeared entirely within about forty-eight hours, and that it could not be found in the mouths of the other children. The experiment, therefore, was negative. It substantiated, however, the experience of Dr. Bloomfield.

DR. RUSSELL L. CECIL, New York: Dr. Bloomfield's experiments have an interesting bearing on some experiments which we have recently carried out on the effect of injecting virulent influenza bacilli into the nose and throat of healthy volunteers. If a virulent culture is used, symptoms usually appear in six or eight hours. The changes most commonly noted were headaches, rhinitis, sore throat, tracheitis, leukopenia and general malaise. None of the subjects had any fever.

Effect of Therapeutic Doses of Digitalis on the Contraction of Heart Muscles

DRS. ALFRED E. COHN and ROBERT L. LEVY, New York: That digitalis causes alterations in the heart resulting in changes in the form of the electrocardiogram is now well known. No evidence has been presented, however, to show that the amount of digitalis required—30 per cent. of a lethal dose—is beneficial, except in cases of fibrillation of the auricles in which block of auricular impulses, mainly through stimulation of the vagus nerves, takes place. A beneficial action must be based on the ability of the drug to increase the

volume output of the heart, and it must be able to do this in therapeutic doses, that is to say, in doses that influence the T wave of the electrocardiogram or reduce the rate in auricular fibrillation. We have accordingly injected this amount into the veins of dogs, eleven of which received the tincture of digitalis, and nineteen of which received g-strophanthin; and into cats, five of which received g-strophanthin, and nine tincture of digitalis. Alterations in volume output were studied in curves obtained by the use of the Roy and Adami myocardiograph. The curves represent longitudinal linear alterations in the form of ventricles, and under the conditions of cardiac contraction may represent changes in volume of the cavities and consequently of volume output.

The significant results concern the effect of these two drugs on the T wave and on the degree of contraction. The degree of contraction changed in the greater number of the thirty dogs that were studied; the T wave in more than half. In cats the T wave usually changed, the degree of contraction decreased in more than half. The effect on contraction differed, therefore, in cats and dogs. In seven dogs and thirteen cats the record of the blood pressure in the femoral artery was added to the other records. Except in one dog and four cats, the blood pressure usually rose. With tincture of digitalis a significant fall of pressure often preceded a rise.

Anesthesia and operative procedures, it was thought, might disturb the electrocardiogram. Experiments were therefore made on dogs in which electrocardiograms and blood pressure records were taken without an anesthetic and without operation. The electrocardiograms were taken in the usual way. The blood pressure curves were obtained in dogs previously prepared by a method described by Van Leersum. By this method a long stretch of one carotid artery was enclosed in a stretch of skin included between two parallel incisions. The tube containing the artery lay free of the neck, and was surrounded by a small rubber cuff. Water transmission to a mercury manometer permitted the taking of records. Minimum and maximum oscillations after the manner of Erlanger indicated systolic and diastolic pressures. It has been found in the few experiments that have so far been performed that T wave changes occurred uniformly and that the blood pressure usually rose, the increase varying from 20 to 66 mm. of mercury.

With doses of therapeutic range, equal to 30 per cent. of the calculated lethal dose, digitalis and strophanthin (1) increased the contractile function of the cardiac muscle, and by so doing increased the volume output. This effect supplies a firm basis for the statement that these drugs may exercise a beneficial action. (2) At the same time, the T wave is usually altered, and (3) there is a transient elevation of blood pressure.

Certain Differences in the Action of Strophanthin and Digitalis in Patients

DRS. ALFRED E. COHN and ROBERT L. LEVY, New York: It is highly desirable to have for use in clinical medicine a safe, effective preparation of the digitalis series for intravenous use. The drug chosen was crystalline strophanthin, as it is a pure substance having definite chemical and physical properties. The crystalline substance employed was isolated from seeds of *Strophanthus gratus*, chemically identified, and biologically standardized by the cat method of Hatcher. The average cat unit was found to be 0.104 mg. per kilogram. For use in the clinic the crystals were dissolved in fiftieth molar phosphate solution with p_{H} 7.0, and autoclaved in hard glass ampules. In this manner alterations in reaction of the solution were prevented, and biologic potency was preserved. Equivalent amounts, in terms of cat units, of strophanthin by vein and of digipuratum by mouth were administered to patients. In this way a series of comparable observations both in the same and in different individuals was obtained. The strophanthin effects could then be viewed with reference to known and fairly constant digitalis standards. While the treatments were being given, electrodes leading to the string galvanometer were kept constantly in place, and curves were made at intervals of fifteen minutes during the first three hours, and then at half-hour intervals for the second

three hours. Another electrocardiogram was usually made the same evening and once daily thereafter until the curve had resumed the form seen in the control. Strophanthin was given usually in two doses at an interval of one hour—the first of from 0.4 to 0.5 mg., the second of from 0.3 to 0.5 mg. Digitalis was administered in comparable doses from 0.7 to 1.0 gm. and at the same intervals in the same patient on different occasions. The giving of relatively large doses, as recommended by Eggleston, has been found feasible. Rarely has it been necessary in auricular fibrillation to give more than 1 gm. (10 cat units) to produce the desired effects.

No serious untoward effects were observed after strophanthin. The onset of abnormal rhythm, namely, ventricular premature beats and ventricular ectopic tachycardia, occurred in 52 per cent. of fibrillators and in 12.5 per cent. of the cases with normal rhythm. Such toxic effects occurred always within twenty minutes of the injection of the dose causing them, and disappeared within eight hours. Nausea and vomiting were noted in 10 per cent. of cases. Comparable doses of digitalis by mouth caused undesirable effects in a much smaller percentage of observations.

We would conclude: First, that crystalline strophanthin, dissolved in fiftieth molar standard phosphate solution and sealed in hard glass ampules, may be kept for at least six months without loss of biologic potency, and secondly, that comparison in patients of the effects of comparable doses of strophanthin by vein and digitalis by mouth showed that: (a) the action of strophanthin is more rapid and is of shorter duration; (b) the T wave of the electrocardiogram is less frequently altered by strophanthin than by digitalis, and (c) toxic effects, though not of serious import, followed more often after the injection of strophanthin than after the administration of digitalis.

The Effect of Foreign Protein Therapy in Lobar Pneumonia

JOSEPH L. MILLER, M.D., Chicago: Fifteen consecutive patients with lobar pneumonia entering Cook County Hospital were treated by a single intravenous injection of typhoid vaccine. The dosage used was 30 millions, the minimum amount required to give a chill. All reacted by a rise in temperature and a leukocytosis. In nine patients the vaccine did not modify the course of the disease. In six, the patient was detoxicated following the injections. The pulse, temperature and respiration returned to normal, the cough and pleural pain subsided, and the patient stated that he felt much better. In three of the six cases the improvement was temporary, as after the lapse of from twelve to twenty-four hours the symptoms returned with unmodified severity. In three cases the detoxication was permanent; however, the patients had a moderate temperature for from three to four days, to the time at which the crisis would normally appear. They were, however, entirely free from evidence of intoxication. There was no relation between the severity of the chill, the temperature reaction and degree of increased leukocytosis, and the beneficial results of the vaccine.

Distribution of Carbon Dioxid Between Cells and Plasma

DRS. J. H. MEANS and L. W. SMITH, Boston: The manner in which carbon dioxid is transported from tissues to lungs by blood has recently been the subject of considerable discussion. We have undertaken a study of the distribution of carbon dioxid between cells and plasma. Samples of blood were drawn from the arm vein or artery under oil, and analysis made of the carbon dioxid content, both of the whole blood and, after centrifugation, of the plasma, by the method and with the apparatus of Yandell Henderson. At the same time the proportion of cells to plasma in each sample was determined by hematocrit observations, and the relative amounts of carbon dioxid in the cells and plasma calculated therefrom. In a series of ten normal venous bloods, the total carbon dioxid varied from 50 to 60 per cent. by volume, the average being 55.2 per cent. by volume. The plasma of a unit of the same bloods contained from 31.1 to 40.8 per cent. by volume, the average being 35.3 per cent. by volume, while the cells contained from 17.2 to 24.9 per cent. by volume, the average being 20.1 per cent. by volume. In

four normal subjects, samples of arterial and venous blood were drawn within a few minutes of each other. The average amount of carbon dioxide in the plasma of a unit of the four arterial bloods was 35.3 per cent. by volume, and of the four venous bloods, 35.8 per cent. by volume. In the cells of a unit of the four arterial bloods, there was an average of 14.2 per cent. by volume of carbon dioxide, and in the cells of the four venous bloods an average of 21.5 per cent. by volume. In other words, the amount of carbon dioxide in the plasma of arterial and venous blood is identical, whereas, when blood is aerated in the lungs, an average of 7.3 per cent. by volume of carbon dioxide is lost from the cells. The transport of carbon dioxide, therefore, is accomplished by the cells, not by the plasma of the blood. In the venous bloods from nine patients with severe anemia, the average amount of carbon dioxide in the plasma of a unit of blood was 52.4 per cent. by volume, and in the cells, 5.8 per cent. by volume. The average total carbon dioxide of these bloods was 58.3 per cent. by volume. Therefore, in anemia the total amount of carbon dioxide in the blood is essentially normal; but in its distribution between cells and plasma, there is relatively less in the cells and more in the plasma than in normal bloods. This, however, is merely because of the smaller relative volume of cells in anemia. The average actual concentration of carbon dioxide in the cells of our fourteen normal venous bloods was identical with that of the bloods of our nine patients with anemia.

DISCUSSION

DR. FRANKLIN C. McLEAN, New York: The results reported are apparently in confirmation of the considerations recently developed by L. J. Henderson, who has shown that the dissociation constant of oxyhemoglobin, as an acid, is about nine times that of reduced hemoglobin. Consequently, in passing through the tissues, and in losing oxygen, the concentration of hydrogen ions in the red cells tends to decrease. The equilibrium between the cells and plasma is maintained, in part at least, by the migration of carbonic acid from the plasma to the cells. It is not necessary, therefore, to assume from the observations here presented that a direct combination of hemoglobin and carbon dioxide is responsible for the increase in carbonate content of the cells.

DR. JAMES HOWARD MEANS, Boston: As far as we could discover, the carbon dioxide carrying power of the cells in anemia is identical with that of normal cells. The smaller amount of carbon dioxide carried by the cells in anemia is due to the smaller proportion of cells in a unit of blood. It is highly probable that the cells carry the carbon dioxide because of the increase in the acidity of hemoglobin when it takes up oxygen, with a resulting decomposition of bicarbonate and liberation of carbon dioxide, according to the formula of L. J. Henderson.

The Constancy of the Volume of the Blood Plasma in Disease

DRS. A. V. BOCK and G. R. MINOT, Boston: The vital red method of Keith, Rowntree and Geraghty was used to estimate the blood plasma volume in five normal and twenty-five abnormal individuals. The total blood volume was then calculated from hematocrit determinations. The pathologic conditions studied include extremes in content of total corpuscles, a wide range of total blood volumes, and cases with and without edema. The results indicate a remarkable constancy of plasma volume in disease comparable to that known to exist in the normal, namely, about 50 c.c. per kilogram of body weight. In conditions with edema and anasarca, it has been found that the blood plasma per kilogram of body weight is the same as in the absence of edema. After hemorrhage, dilution of the plasma volume tends to occur rapidly until the normal plasma level is reached, after which it remains fixed in amount. Previous figures concerning the blood volume in pernicious anemia and chlorosis, usually quoted in the literature, are too great. Variations in the total blood volume in disease are due chiefly to differences in total content of corpuscles. For example, a case of polycythemia vera, with a total of 75 trillion red cells in the body, was found to have essentially the same plasma volume in relation to the body weight as a case

of pernicious anemia with a total of three trillion red cells. Certain exceptions to the proposition of a fixed plasma volume do exist, such as in hemorrhage and shock, edema of the lungs, after excessive sweating, in severe diarrhea, and probably as a result of changes in altitude. Emphasis has been placed on the importance of a proper tissue fluid reserve in order to keep the plasma volume at a physiologic level. There is a possible source of error in blood volume determinations that depend on dilutions of whole blood, or primarily on corpuscle content of the blood. Methods that determine the plasma volume directly seem to offer more accurate results than those demanding the use of whole blood.

The margin of error of the vital red method is such as to result in variations in duplicate determinations up to 10 per cent. The colorimetric reading, necessary for the determination of the plasma volume, may be difficult owing to a difference in color of the solutions. This difference is usually attributed to hemolysis, but spectroscopic examination of many specimens has failed to verify such an explanation. Cases of hypertension are likely to have plasma volumes on the lower limit of normal, as Dr. Rowntree suggests. As to the relation of blood volume to body surface, the formula of Dreyer as applied to man, $B.V. = \frac{B.W. \cdot 0.72}{0.67}$, gives a figure for the total blood volume greater than has been reported by any other method.

A Further Study of the Carotinoid Pigments in Human Blood and Tissues

DRS. ALFRED F. HESS and VICTOR C. MYERS, New York: Not only carotin is frequently present in human blood, but sometimes also xanthophyll, a carotinoid pigment of different solubility. These substances vary greatly in amount, but are found in the blood of most adults in such quantities as to discolor the plasma, but not the skin. As might be expected, they are present to a greater degree in the blood of adults than in that of infants, who are on a milk diet. Carotin has been found in the colostrum, and a trace of it has been noted in the plasma of a new-born infant. However, the blood of the mother may contain a considerable amount of this pigment and yet the blood of her new-born infant be free of it, showing that the pigment does not pass through the placenta.

These pigments do not discolor the sclera unless they are present in very large amounts, the antithesis of what obtains in relation to the bile. This is probably due to the fact that the bile injures the endothelium of the vessels and thereby leads to their permeability. Carotin seems to have a slight photodynamic effect, causing a mild desquamation of the skin where it is exposed to the light.

DISCUSSION

DR. ALFRED F. HESS, New York: I am unable to state in reply, to the questions asked, whether or not there is any relationship between freckles and the carotinoid pigments. It is, however, quite possible, especially in view of the photodynamic quality of the pigment. This entire question has a clinical point of view. Some patients who are diagnosed as having liver trouble and some metabolic disturbance are undoubtedly suffering from carotinoid pigmentation of the skin. Recently I saw a child who came under this category, and had been treated with calomel for a considerable period, in view of the fact that its liver was slightly large and its color slightly yellow. When the carotinoid food was removed from the diet, its skin became white.

High Protein Diets and Arteriosclerosis in Rabbits

DRS. L. H. NEWBURGH and THEODORE L. SQUIER, Ann Arbor, Mich.: In the studies dealing with the effect of high protein diets on the kidneys of rabbits, it was noted that the animals which ate such diets for a number of months showed at necropsy widespread arteriosclerosis of the aorta. It was further noted that the extent of the vascular disease was roughly proportional to the duration of the high protein feeding. In another group of animals fed a diet made of a mixture of dried powdered beef and bread flour in the proportion of 1:2, the notes dealing with the condition of the

aorta show that the aortas of two rabbits that lived on this diet four weeks and six weeks each presented a tiny patch of arteriosclerosis. Four animals that ate the diet for from three months to seven months possessed aortas that showed very many irregular slightly raised, partly ulcerated plaques and streaks, extending from the aortic valves to a short distance below the diaphragm.

The two obvious sources of error in assuming that the vascular lesions observed bear a casual relationship to the diet are, first, that arteriosclerosis may be a lesion of very frequent occurrence in laboratory rabbits; and second, that arteriosclerosis may be common in old rabbits and that the experimental rabbits in which the arteriosclerosis was found were old and would accordingly be expected to show a high incidence of the vascular disease. As a control for the first possible source of error we examined fifty-nine rabbits used in the laboratory for other purposes. The aortas of all of these rabbits, with two exceptions, were normal. In the aorta of each of these two rabbits we found a single very small sclerotic patch. The second possible source of error will not account for the vascular lesions found in the group of animals that ate the meat mixture, as these rabbits were not senile. The oldest was not older than 14 months when killed.

The microscopic appearance of the vascular lesions made it clear that we were dealing with true arteriosclerosis analogous to that which is commonly found in the human being. The proportionality existing between the length of the high protein feeding and the amount of vascular injury serves further to emphasize the view that the arteriosclerosis observed in rabbits that lived on high protein diets was directly or indirectly caused by these diets.

The Basal Metabolic Rate Before and After Surgical Treatment in Adenoma of the Thyroid With and Without Hyperthyroidism and in Exophthalmic Goiter

DR. WALTER M. BOOTHBY, Rochester, Minn.: According to Plummer's classification there are two separate and distinct types of hyperthyroidism, each due to a different pathologic change in the thyroid gland: In the one type, the hyperthyroidism associated with the clinical syndrome of true exophthalmic goiter is always accompanied by diffuse hypertrophy and hyperplasia of the thyroid gland; in the other type the hyperthyroidism, not associated with this typical diffuse hypertrophy and hyperplasia, but with the occurrence of adenoma in the gland, is due to the adenoma, and the resulting syndrome is distinguishable from that occurring in true exophthalmic goiter.

The syndrome associated with the hyperthyroidism from adenoma of the thyroid is considered by Plummer as a distinct clinical entity and may be defined as a disease associated with adenoma, characterized by an increased basal metabolic rate excited by an excess of the normal thyroid hormone in the tissues. At about middle age the adenomatous tissue gradually begins to furnish an excessive amount of the apparently normal thyroid hormone (thyroxin-Kendall) and this produces the increased metabolic rate and intoxication clinically evidenced by nervousness, tremor, tachycardia, loss in strength and weight, and a tendency to hypertension, and in the later stages myocardial disintegration. The underlying cause or stimulus that activates the thyroid to adenomatous growth and oversecretion is not known.

Detailed metabolic rate and blood pressure studies are reported on seventy-five cases of adenoma with hyperthyroidism in which the average basal metabolic rate before treatment was +35 per cent. and after operation +7 per cent. Similar studies of 201 cases before treatment are also given in which the average basal metabolic rate was +28 per cent. In contrast, the average basal metabolic rate in 167 cases of adenoma without clinical evidence of hyperthyroidism was +2 per cent.; eighteen with an average basal metabolic rate before operation of -4 per cent. remained virtually unchanged, -8 per cent. as a result of thyroidectomy.

Three groups of exophthalmic goiter cases of varying degree of severity were studied. In thirty-six cases of the severest type the average metabolic rate before treatment was +66 per cent; these patients were subjected to rest

in bed and two ligations at an interval of a week or more; and within ten days after the second ligation the basal metabolic rate was +50 per cent. These patients after three months' rest at home returned to the clinic and were found to have a basal metabolic rate of +42 per cent., with corresponding clinical improvement; within two weeks after thyroidectomy these patients were reading +19 per cent. In a second group, comprising fifty-two moderately severe cases, subjected to a single ligation and thyroidectomy from one to two weeks later, the basal metabolic rate before treatment was +52 per cent.; in twenty-two of these cases the basal metabolic rate ten days after the preliminary ligation was +41 per cent.; within two weeks after thyroidectomy the basal metabolic rate in the entire group had fallen to +15 per cent. In fifty-two cases of mild exophthalmic goiter in which a primary thyroidectomy was performed, the average basal metabolic rate before treatment was +36 per cent., and two weeks after operation was +8 per cent.

DISCUSSION

DR. JAMES HOWARD MEANS, Boston: I agree that the importance of the metabolism determination in thyroid disease is about the same as the determination of the temperature in febrile diseases. It is proper now to say a word of warning in this matter. We could doubtless treat typhoid fever fairly intelligently without basal metabolism determinations. Nevertheless, if we recognize that the metabolic rate does not tell us everything about one case of exophthalmic goiter, we shall be very glad to have the accurate information of the degree of his hyperthyroidism that the metabolic rate gives us. Thus, if we keep in mind the limitations of this highly technical procedure, we shall find it exceedingly valuable in accurately following in a quantitative way the progress of the disease. In any given patient the pulse curve and metabolic curve are essentially parallel. Plotting from the same base line, we find that some patients have a relatively greater rise in pulse rate than in metabolism and vice versa.

Biologic Study of Hemolytic Streptococci from Throats of Patients Suffering from Scarlet Fever.

DRS. A. R. DOCHEZ and WALTER P. BLISS, Baltimore: Utilizing the technic for streptococcus agglutination recommended by Dochez, Avery and Lancefield (*J. Exper. Med.* 30:179 [Sept.] 1919), a series of twenty-five strains of *Streptococcus hemolyticus*, isolated from the throats of patients suffering from scarlet fever, were tested against Dochez and Avery's five type antistreptococcal serums of nonscarlatinal origin, namely, Types S3, S23, S32, S60 and S84, and against four antistreptococcal serums made from strains isolated from patients with scarlet fever (Dochez and Avery's Type S273, and the author's strains 23, 24 and 25). Twenty, or 80 per cent., of the twenty-five strains studied were agglutinated by all four antistreptococcal serums of scarlatinal origin, in most instances in as high dilution as the homologous organism, which averaged from 1:160 to 1:640. None of these strains of scarlatinal origin were agglutinated by the five antistreptococcal serums derived from strains of non-scarlatinal origin, except in the case of Serum Type S84, a rabbit serum which showed a tendency to nonspecific agglutination of streptococci and agglutinated six of the twenty-five strains. On the other hand, only three of seventeen strains of nonscarlatinal origin isolated from throat cultures in tonsillitis, pus from abscesses, and blood cultures were agglutinated by these antistreptococcal serums of scarlatinal origin, and according to the history of these three cases they may have been either atypical scarlatinas or scarlatinal contacts.

From this study, therefore, it would appear that a great majority (80 per cent.) of strains of *S. hemolyticus* isolated from the throats of patients with scarlet fever belong to a specific biologic type as determined by the reaction of agglutination. It is possible that the heterogeneous strains found may be accidental dwellers in the throat, and that a more careful selection of colonies may reveal a still higher proportion of unit type organisms.

- *Influenza and Tuberculosis. J.-B. Anderson, Jr., and A. Peters, Jr., Loomis, N. Y.—p. 71.
*Use of Sodium Gynocardate "A" in Pulmonary Tuberculosis. M. Biesenthal, Chicago.—p. 84.
*Secondary Invaders of Tuberculous Lungs. J. N. Hayes, Pittsburgh.—p. 84.
Experimental Study of Action of Ultraviolet Light on Intradermic Tuberculin Reaction. E. Mayer, Saranac Lake, N. Y.—p. 100.
Classification to Facilitate Selection of Patients for Work in Tuberculosis Sanatorium. W. T. Cannon, New York.—p. 112.
Ideals in Treatment of Tuberculosis. S. A. Knopf, New York.—p. 118.

Influenza and Tuberculosis.—Anderson and Peters supplement a previous communication on epidemic influenza among patients and employees of the Loomis Sanatorium, with a further analysis of the histories of patients who had influenza before entering the sanatorium and a record of the incidence and fatality of this disease among former patients. They also give a critical review of recent literature on the subject. Of 1,227 traced former patients, seventy contracted influenza and sixteen died of the disease. Of 199 new patients admitted between Nov. 1, 1918, and Nov. 1, 1919, forty-two gave a definite history of influenza. Of these forty-two, eighteen knew they had tuberculosis prior to their influenza, while twenty-six gave a history of previous symptoms that were presumably tuberculous. In twelve cases the onset of tuberculosis was definitely postinfluenzal. The authors conclude that tuberculosis does not confer an immunity to influenza; that influenza is not less severe among the tuberculous; that among their own patients the case fatality was higher than among the general population; that among a certain number of individuals influenza marks the inception of pulmonary tuberculosis, and that to ignore and deny the possibility of pulmonary tuberculosis as a sequel is to defer unduly diagnosis and early treatment.

Sodium Gynocardate "A" in Treatment of Pulmonary Tuberculosis.—Sodium gynocardate "A" is a salt of chaulmoogra oil. It has recently been suggested as a possible remedy for tuberculosis. Biesenthal has employed it in treating ten patients. Not a single patient showed any improvement of signs or symptoms and there were no sputum changes from positive to negative. In two cases acute reactions followed the injections.

Other Bacteria in Tuberculous Human Lungs.—Hayes reports the bacteriologic findings from the study of the lungs of fifty-two tuberculous patients. A number of concomitant micro-organisms, *Streptococcus hemolyticus* and *S. viridans*, *Staphylococcus albus* and *S. aureus*, pneumococcus, *Micrococcus catarrhalis*, Pfeiffer bacillus, etc., were encountered. *Streptococcus hemolyticus* was found in a large percentage of the throats and washed sputums examined. It was also found at necropsy in the caseous areas and cavities of the same patient's lungs.

Annals of Surgery, Philadelphia

April, 1920, 71, No. 4

- *Treatment of Arteriovenous Aneurysms by Intrascapular Method of Suture (Endo-Aneurysmorrhaphy): Special Reference to Transvenous Route. R. Matas, New Orleans.—p. 403.
*Arteriovenous Fistula; Analysis of 447 Cases. C. L. Callander, Baltimore.—p. 428.
Treatment of Malignant Tumors of Thymus Gland by Radium; Report of Nine Cases. H. H. Janeway, New York.—p. 460.
Malignant Disease of Lungs; Early Recognition and Progressive Development, as Studied by Roentgen Rays; Treatment. G. E. Pfahler, Philadelphia.—p. 472.
Circumscribed Panmural Ulcerative Cystitis. F. E. Keene, Philadelphia.—p. 479.
*Hypospadias; Operation of Bucknall. J. W. Churchman, New York.—p. 486.
Projectile Fractures of Long Bones. K. Speed, Chicago.—p. 493.
*Form of Splint Available in Treatment of Fractures of Neck of Femur. H. C. Masland, Philadelphia.—p. 501.
Anhydrous Cocain Spinal Anesthesia. J. R. Wells, Philadelphia.—p. 504.

Endo-Aneurysmorrhaphy.—Matas details personal experiences which illustrate the practical application of the intrascapular method of suture which he devised and advocated for the cure of arterial aneurysms (endoaneurysmorrhaphy), and found equally advantageous in its cure of the most frequent types of the bivascular or arteriovenous aneurysms.

Arteriovenous Fistula.—The cases analyzed by Callander are taken from the literature. Although the name of the reporter is given in each instance, the bibliographic reference is otherwise incomplete.

Operation for Hypospadias.—Churchman reports a case of penoscrotal hypospadias cured by the operation of Bucknall. He also reviews all the operative procedure employed for these cases.

Splint for Fracture of Neck of Femur.—Masland's splint is made from bale strap iron bent to conform to the line of the trunk and the limb.

Boston Medical and Surgical Journal

May 20, 1920, 182, No. 21

- Doctors in Uniform. H. W. Dana, Boston.—p. 521.
Urologic Cases. W. C. Quinby, Boston.—p. 525.
Fat Transplantation After Excision of Cicatricial Contraction of Lower Jaw. W. R. Morrison, Boston.—p. 529.
*Case of Apparent Paradoxical Respiratory Arrhythmia of Heart. D. White, Boston.—p. 531.

Paradoxical Respiratory Arrhythmia of Heart.—A case is reported by White showing a decrease in ventricular pulse rate with inspiration and exercise instead of the normal increase. The apparent paradox was caused by the production of heart block by increase of auricular rate plus depressed auriculoventricular conduction.

Bulletin Johns Hopkins Hospital, Baltimore

April, 1920, 31, No. 350

- Venous Thrombosis, Pulmonary Infarction and Embolism Following Gynecologic Operations. H. H. Hampton and L. R. Wharton, Baltimore.—p. 95.
*Fate of Bacteria Introduced into Upper Air Passages. Reaction of Saliva. A. L. Bloomfield and J. G. Huck, Baltimore.—p. 118.
*Pyelitis, Ureteritis and Cystitis Cystica. V. C. Jacobson, Madison, Wis.—p. 122.
*Apparatus for Measuring the New-Born. A. H. Schultz, Washington, D. C.—p. 131.
Unusual Case of Tuberculous Salpingitis. J. P. Greenberg, Baltimore.—p. 132.

Reaction of Saliva.—Study of freshly expectorated saliva from normal people made by Bloomfield and Huck shows that the reaction tested by the colorimetric comparison method may vary within considerable limits—6.0 to 7.3—although 80 per cent. of the specimens fell within the range of 6.6 to 7.1. The reaction varied in different individuals and in the same individual at various times apparently without any definite or constant relation to the time of day or to the ingestion of food or fluid. It was temporarily altered by mouth washes such as Dobell's solution, but only for a short time (thirty minutes). Internal administration of acid and alkali did not seem to influence the reaction of the saliva in any definite manner. Observations on a group of patients suffering from a variety of diseases showed no constant relation between the reaction of the saliva and any particular disease, although the variations covered a slightly wider range (p_H 5.8 to p_H 7.5) than was found in the case of the normal group.

Pyelitis, Ureteritis and Cystitis Cystica.—The condition described by Jacobson is a cystic inflammation of the pelvis, ureters and bladder. It occurs in persons of either sex, in 95 per cent. of cases in senile arteriosclerotic individuals from whom a history of previous urinary inflammation or other disturbance can be obtained. Three typical cases are reported in detail, all in aged men, two of whom had a history of prostatic trouble and the third bilateral pelvic calculi. In one a double ureter was present. In view of the large number of cell "nests" of von Brunn in the ureter and bladder of senile individuals and the high incidence of urinary tract infections in the aged, Jacobson believes that cystic inflammation of these organs is relatively common in this class of patients.

Measuring the New-Born.—The apparatus designed by Schultz consists in principle of a horizontal board on which the baby is placed on its back, of one perpendicular board firmly attached to one end of the horizontal or base board, which has to be touched by the top of the head of the baby, and another (sliding) perpendicular board which can be brought into contact with the buttocks for the measuring of the sitting height or with the soles of the feet for measuring the standing height. The distance between these two perpendicular boards constitutes the required measurement and is read off from a scale attached to the horizontal board. The movable vertical board is mounted on a brass saddle, which slides on the horizontal board and holds the perpendicular board at right angles to the main axis of the base board. On each of the two lateral edges of the base board a brass strip is inlaid and one of these is ruled in millimeters from 200 to 650, zero being at the end of the base board where it meets the firm perpendicular board. The range of ruling is sufficient for measuring from the sitting height of a fetus at the end of the sixth month to the standing height of an exceptionally large new-born. The brass saddle rests with its lateral portions on the two brass strips; the center of the saddle is slightly raised to reduce friction to let only metal ride on metal. A small area on the edge of the saddle over the ruled brass strip, on a plane with the movable perpendicular board, is tapered to a knifelike edge to allow accurate reading of the scale.

- *Basal Metabolic Rate in Exophthalmic Goiter (1917 Cases); Description of Technique Used at Mayo Clinic. I. Sandiford, Rochester, Minn.—p. 71.
- Structure of Thyroid and Its Qualitative Variations. V. M. Buscaine, Florence, Italy, and G. Vercellini, St. Paul.—p. 88.

Relation of Thyroid and Hypophysis to Growth and Development.—The Hoskins find that a preparation of the anterior lobe of beef hypophysis, which contains some form of iodine, 1:200,000 of fresh substance, when administered to normal frog larvae will bring about a precocious metamorphosis, resulting in the production of frogs the size of which varies with the size of the larvae at the beginning of the experiment. Such frogs have little vitality. If permitted to remain exposed to the air they die and dry down almost flat, losing their shape and there remains but a very small percentage of the original volume. When the pituitary preparation was administered to thyroidless larvae which would otherwise have remained in the larval form more or less indefinitely, a beginning of metamorphosis occurred within twenty-four hours; it progressed somewhat more slowly than in the other experiments; but it ultimately became nearly complete by the time the animals were either killed or died spontaneously. The authors regard the results obtained as due to a stimulation of natural general metabolic processes, either directly or indirectly, but the exact nature of this action is not known. The effect is both progressive, as seen especially in the skeletal and cutaneous development, and retrogressive, as seen especially in the digestive tract and tail. It is very doubtful that the action of the anterior pituitary substance is due merely to its iodine content, although such may be the case. Other tissues with traces of iodine will not produce the same effect as the pituitary. It is quite possible that the initial stimulation in hypophysis feeding is exerted on the calcium and phosphorus metabolism as is indicated by skeletal changes in these experiments, although intestinal transformation also begins very early.

Chronic Epinephrinism.—The history is recorded by Hoxie and Morris of a case of six years' duration in which the

patient had taken approximately 7 c.c. of epinephrin daily, for the most part with a hypodermic needle. She had occasionally used morphin and chloroform. Sudden death occurred. Aside from a collapsed right lung and a beginning aortic sclerosis, the chief postmortem findings were congestion of the abdominal viscera, similar to that found in animals dead from epinephrin administration.

Effect of Feeding Thyroid on Pancreas.—Feeding dry-thyroid in dosage of 0.5 to 0.1 gm. to rats resulted in a marked decrease of the diastatic activity of the pancreas varying from 40 to 92 per cent. This was accomplished by a diminution of the acidophil granules of the pancreas cells. Large doses of thyroid were more effective than small, but the effects in different animals were variable. The diastase content of the intestinal juice was also decreased in some cases by the thyroid. In such positive cases the appetite was markedly depressed and the feces were soft; in extreme cases they contained considerable quantities of fat. Thyroid feeding frequently resulted also in marked enlargement of the pancreas. In such cases the pancreatic diastase was often decreased even when the amount of food consumed and the intestinal diastase were augmented. Hoshimoto stated that the decrease cannot be ascribed to general metabolic perturbation since it frequently antedated any evidence of such. It is rather ascribed to stimulation of diastase discharge from the pancreas.

Thyroid Diabetes.—Rohdenburg cites a family in which glycosuria was increased in intensity after oral administration of either thyroid gland or suprarenal. One member of this family was cured of his glycosuria after a partial thyroidectomy. Another patient who had previously had a portion of his thyroid removed for exophthalmic goiter developed glycosuria several years later. The glycosuria in this case also disappeared after extirpation of more of the thyroid gland.

Metabolism in Exophthalmic Goiter.—In 182 cases of exophthalmic goiter before any treatment was instituted the average metabolic rate was plus 51 per cent., with an average pulse rate of 115. In thirteen patients whose average metabolic rate, as outpatients, was plus 59 per cent., with an average pulse rate of 115, the average metabolic rate fell to plus 46 per cent., and the average pulse rate to 108 as a result of approximately one week's complete rest in bed. In five patients whose average metabolic rate, determined within two to five days after they entered the hospital, was plus 59 per cent., and the pulse 118, after a further rest in bed of approximately one week's duration there was a definite improvement in their condition, as shown by a fall in the metabolic rate to an average of plus 48 per cent. and pulse to 104. The effect of a single ligation was studied in sixteen cases. The basal metabolic rate taken after the patient had had several days' rest in bed and within five days before the first ligation was plus 54 per cent. and pulse 116. One week after the single ligation the average metabolic rate had decreased to plus 44 per cent. and the pulse to 112. The effect of the second ligation is likewise a general improvement in the patient's condition as evidenced by a decrease in the metabolic rate. In twenty-two patients there was an average decrease in the basal metabolic rate from plus 46 to plus 39 per cent., and in the pulse from 115 to 107 with a gain in weight from 46.4 to 54.5 kilograms in the determinations made a few days after the second ligation as compared with the data obtained after three months' rest at home and just previous to thyroidectomy. A definite improvement from thyroidectomy in those patients who had had two ligations and a three months' rest was shown two weeks following operation by a decrease in the basal metabolic rate from plus 39 to plus 16 per cent., and in the pulse rate from 107 to 89. In another group of nineteen patients with exophthalmic goiter in whom the preliminary basal metabolic rate varied between plus 13 and plus 50 per cent., giving an average of plus 31 per cent. with an average pulse of 104, and in whom primary thyroidectomy was done without any other preliminary treatment, except for a short rest in bed, the basal metabolic rate fell, about two weeks after operation, to plus 5 per cent. and the pulse to 48.

- Bouillon Chnes as Substitute for Beef Extract or Meat in Nutrient Medium. Z. N. Wyant, East Lansing, Mich.—p. 189.

Modified Loeffler's Flagella Stain.—The modification of Loeffler's method proposed by Shunk differs from previous modifications chiefly in the use of a solution of anilin oil in alcohol (1:4) in connection with the ferric-chlorid tannic acid mordant which was Bunge's modification. By using one drop of this solution with about eight drops of the ferric tannate solution, applied together on the coverglass, all necessity of heating the mordant or the stain is obviated. The stain recommended is a special methylene blue made by adding an alcoholic solution of anilin oil (1:4) to Loeffler's methylene blue in the ratio of 1:10. The chief advantages of the process are said to be (1) its simplicity, (2) the use of solutions that keep well, (3) the use of all solutions at room temperatures, and (4) the high percentage of successful attempts, even in the hands of inexperienced students.

- Gun-Shot Wounds of Urethra. J. A. C. Colston, Baltimore.—p. 185.
- *Epithelial Hyperplasia in Congenital Cystic Kidneys. C. A. McKinlay, New Haven, Conn.—p. 195.

Effect of Feeding Prostate.—The effect of feeding desiccated prostatic substance from various animals on the growth and development of a number of species of tadpoles was studied by Macht. It was found that prostate feeding tends to stimulate both the growth and metamorphosis of the larvae of the frog, toad and salamander. These observations speak in favor of an internal secretion of the prostate gland.

Congenital Stenosis of Ureteral Orifices.—Wason reports the case of a poorly nourished boy, 7 months of age, who was admitted to the hospital on account of diarrhea. Physical examination was negative. At necropsy there was found double hydronephrosis with dilated tortuous ureters which ended in cystic dilatations in the small vesical cavity. Grossly, the ureteral orifices were not visible; by serial section they were found to be stenotic and to measure from $\frac{1}{8}$ to $\frac{1}{6}$ mm. in diameter. In addition there was present a valve extending from the lower end of the verumontanum to the right urethral wall.

Lymphosarcoma of Prostate.—The early clinical picture in Quinby's case was essentially that of an acute infection, and this condition overshadowed the tumor growth which locally was of insignificant size and was interpreted only with difficulty on cystoscopic examination. Following this insidious origin, the early course and general malignancy was so great that death occurred four months after onset of symptoms. Three other cases of lymphosarcoma are recorded in the literature.

Influence of Diet on Antiseptic Properties of Urine.—Hain found that the antiseptic property of normal, drug-free dog

urine toward *B. coli* can be controlled by regulating the diet and the quantity of water ingested. If a definite quantity of liver per kilogram of body weight per day, representing a food high in protein, be fed, the bactericidal property of dog urine is inversely proportional to the quantity of water ingested. If a constant quantity of water be given daily, the germicidal property of dog urine toward *B. coli* varies distinctly with the quantity of animal food high in protein, as liver, ingested. The urine of dogs fed on bread and milk is not germicidal toward *B. coli* or *Staphylococcus albus*. Dog urine has selective germicidal action on *B. coli* when the animals are fed on animal food high in protein, since many specimens from these dogs are fatal to *B. coli* but innocuous to *Staphylococcus albus*.

Epithelial Hyperplasia of Congenital Cystic Kidney.—A case of congenital cystic kidney is reported by McKinlay in which death occurred at the end of the third decade from arteriosclerosis and cerebral hemorrhage. Epithelial hyperplasia of the convoluted tubules with giant cell formation, dilatation of the tubules, papillomatous infoldings, and bud-like sprouts characterized the histologic picture. The epithelial changes were not unlike the pictures that have been described for compensatory hyperplasia in the kidney. It is suggested that the changes in the epithelium and the tubules themselves are expressions of compensatory effort on the part of an organ whose functional capacity has been reduced by primary cystic change.

Medical Record, New York

May 22, 1920, 97, No. 21

- Evaluation of Recent Investigations Concerning Water Metabolism of Body in Relation to Digestive Disturbances and Functions of Blood. J. C. Hemmeter, Baltimore.—p. 857.
- *Splenomegalic Hemolytic Jaundice; Case of Congenital Type. C. L. McVey, Oakland, Calif.—p. 864.
- Prophylaxis and Treatment of Gallstone Disease. S. Weiss, New York.—p. 869.
- Humped, Hooked and Bulbous Noses; Etiology and Treatment. W. W. Carter, New York.—p. 872.
- Remarkable Vitality in Larva of an Insect—*Alaus Oculatus*. R. W. Shufeldt, Washington, D. C.—p. 874.

Congenital Splenomegalic Hemolytic Jaundice.—McVey's patient was aged 18, a female, with a wholly negative family history. Her disease was discovered in the course of a routine examination made on all entrants at the University of California. Her only symptom was lassitude. The principal blood findings were: hemoglobin, 55 per cent.; erythrocytes, 2,400,000; leukocytes, 8,900; poikilocytosis and anisocytosis; increased fragility of red cells.

Nebraska State Medical Journal, Norfolk

- Venereal Problems in Navy. J. A. McGlinn, Philadelphia.—p. 896.
- Group Study from Viewpoint of Internist. O. S. Wightman, New York.—p. 899.
- Unity of Action of Nerves, Circulation and Respiration. P. A. Kane, Chicago.—p. 904.

Neurotic Symptoms in a Child.—When Stern first saw his patient, he suffered from a tic involving the facial muscles, the head, the right arm and the right leg. These symptoms

dated back to the age of 6. He suffered also from fear, manifested mainly in his attitude toward his boy companions and his father. The first symptom which the patient showed was a cackling or crowing sound emitted on all occasions. This continued more or less intermittently for about eighteen months and was then augmented by the development of grunting or growling sounds which then supplanted to a great extent the former symptom. Blepharospasm and facial grimaces appeared, with the tic mentioned above. Stern presents his findings on psychanalysis of this patient and concludes that it was a psychoneurosis.

Pulmonary Tuberculosis. C. R. Woolwine, Davy.—p. 372.

Extra-Uterine Pregnancy, Report of Forty-Seven Cases. C. F. Hicks, Welch.—p. 376.

Effect of Achondroplasia on Menstruation.—The characteristics common to Miller's cases were: both patients presented the typical appearance of achondroplasia; both had mothers slightly under the normal female stature, but perfectly normal in every other way; both were members of large families, their brothers and sisters being normal; no history of other dwarfs in either family, and no evidence of thyroid trouble in either patient or any member of their respective families. One patient, aged 26 years, began menstruating at the age of 2 weeks and continued regularly at twenty-eight day intervals until the age of 24 when she went into the menopause with characteristic nervous and physical phenomena of this condition in the normal female. Pubic hair appeared at about 5 or 6 years of age and at the same time the facial appearance became that of a mature adult. The second patient, aged 25 years, had no indication of the menstrual flow until 21, though for several months preceding the flow there was a sort of general malaise for a few days at from four to six week intervals. Development of the breasts, and pubic and axillary hair appeared about the twelfth or fifteenth year.

*Suggestions for Treatment of Fracture of Radius and Ulna at Middle Third. C. H. Lemon, Milwaukee.—p. 465.

Treatment of Fracture of Radius and Ulna at Middle Third.—Lemon treats all these fractures, without exception, in a supine position with the palm of the hand up so that a plane passed horizontally through the arm and hand would divide the arm and hand into anatomically correct position

of an anterior and posterior surface. In 90 per cent. of the cases he has found plaster of Paris to be the most efficient dressing. The cast is doubly reinforced at the point of fracture and overcorrected, that is, slightly bowed in the direction of extension to the thickness of the plaster, over the site of the fracture. Plaster of Paris should not be used in the treatment of these cases as a primary dressing. It will lead to disaster. For the first four or five days during which the swelling will reach its height, ordinary coaptation splints may be used, the point opposite the fracture being doubly padded to produce overcorrection, and for this primary it is not necessary in my experience to use a splint which extends beyond the elbow joint, but at the end of five days, when the swelling is absolutely under control and when it has usually begun to recede, to treat these cases with a splint or any form of apparatus which does not extend above the elbow joint up the arm to at least one third of its length, Lemon says is to be guilty of gross error.

FOREIGN

Titles marked with an asterisk (*) are abstracted below. Single case reports and trials of new drugs are usually omitted.

British Medical Journal, London

April 24, 1920, 1, No. 3095

*New Views on Pathology, Diagnosis and Treatment of Gastric and Duodenal Ulcer. A. F. Hurst.—p. 559.

*Surprises in Diagnosis. E. L. Spriggs.—p. 563.

*Results of Peptone Treatment of Asthma. A. G. Auld.—p. 567.

*Myoclonic Form of Epidemic Encephalitis. P. Boveri.—p. 570.

Gastric and Duodenal Ulcer.—Hurst is convinced that there is one type of stomach in which a gastric ulcer will develop and another type which is likely to lead to ulceration of the duodenum, if the necessary exciting causes are present, but the latter will not give rise to ulceration at all in an individual with the average normal type of stomach. He believes also that the association of chronic appendicitis with both acute and chronic gastric and duodenal ulcer is too common to be a coincidence, and the greatly diminished tendency to relapse, especially of acute ulcers, following removal of the appendix without interfering with the ulcer, shows that the appendicitis is the primary condition. It probably leads to ulceration in much the same way as the first of the two channels described in connection with dental infection. He is convinced that the tendency to develop a duodenal ulcer is increased by excessive smoking; the nicotine apparently acts through the autonomic nervous system, and increases the hypertonus and hypersecretion of the stomach.

Value of History in Diagnosis.—The diagnoses made in 500 cases are analyzed by Spriggs with reference to their correctness. By means of the history, symptoms, signs, and general condition of the individual patient, an accurate diagnosis was made in 40 per cent. of 500 patients. In over half of the series of 500 cases the preliminary clinical diagnosis was modified or changed after routine investigations had been made.

Peptone Treatment of Asthma.—This treatment has been instructive in respect of the grouping of asthmatic cases. Two main groups occur which show no tendency to pass into each other. One group comprises such as quickly respond to the treatment, and the effect is more or less lasting, the recurrences being infrequent and milder in character. The other group is resistant, and is subdivisible into such as are totally resistant and those in which, by careful immunization, the disease may be largely overcome. Cases of each group are reported in illustration of the treatment and its results.

Myoclonic Epidemic Encephalitis.—Two cases of epidemic encephalitis are reported by Boveri in which the symptoms were not lethargy, but excitement, delirium and myoclonic contractions.

Case of Tuberculous Meningitis with Complete Recovery. H. Barber.—p. 601.

Bronchiectasis.—Among 29,700 patients admitted to the Brompton Hospital during the last twenty years a clinical diagnosis of bronchiectasis was made in 567, or 1.9 per cent. Jex-Blake is of the opinion, however, that bronchiectasis was present in fully 5 per cent. of the patients admitted. The primary disorder from which it resulted in 105 fatal cases so far as could be judged from the histories and postmortem examinations was: chronic bronchitis, 41 cases; pleurisy or pneumonia, 27 cases; bronchial obstruction by a new growth, 27 cases; by foreign body, 6 cases; by aortic aneurysm, 3 cases; by syphilitic stenosis, 1 case. The most interesting of the complications of bronchiectasis is intracranial abscess, fifteen instances of which occurred in 108 fatal cases of the disease. The abscesses were cerebral in nine instances, cerebellar in three, both in two, and in one case meningitis and ependymitis were present, but no intracranial abscess was located. The abscess was single in nine patients, multiple in six, and in one instance from twenty to thirty abscesses were present throughout the brain. In addition two cases of secondary intracranial new growth were recorded in this series: one patient had a primary new growth at the root of the left lung, with secondary deposits in the pancreas and brain; the other a primary endothelioma of a pulmonary alveolus compressing the left bronchus, with secondary growth in the brain. Apart from these intracranial complications, the common complications of bronchiectasis are inhalation or aspiration bronchopneumonia, empyema, gangrene and abscess of the lung, and old or recent pulmonary tuberculosis. The most frequent causes of death were: bronchopneumonia, 34 cases; exhaustion, 34 cases; exhaustion and asphyxia, 8 cases; intracranial abscess, 15 cases. The pathogenesis, symptoms, diagnosis and treatment are discussed in detail.

Antimony in Filariasis.—The results recorded by Rogers appear to indicate that intravenous injections of soluble antimony salts have a definite effect in greatly reducing or causing the disappearance of the filarial embryos from the peripheral blood, presumably as a result of the destruction of the adult filaria, as the effect may last in some cases in an increasing degree for several months after cessation of the treatment. Moreover, clinically favorable results have been obtained in a few cases of filarial fever and elephantiasis. Rogers cautions, however, that as a rather long course of intravenous injections of a highly toxic drug is required to produce this effect, the new method of treatment requires care in its use, and much further experience will be necessary before its precise value can be decided.

*Typhoid and Paratyphoid Triple Lipovaccine or T, A, B-Lipovaccine. K. Ujiie.—p. 1.

*Therapeutic Effect of Lemongrass Oil on Skin Diseases Caused by Animal Parasites. S. Takasugi.—p. 2.

*Case of Erythrocytosis. T. Kanematsu.—p. 3.

Triple Typhoid and Paratyphoid Vaccine.—Ujiie has prepared a triple lipovaccine of typhoid and paratyphoid A and B bacilli by mixing their agar culture first with lanolin and, then, when the mixing was complete, with liquid paraffin. Compared with normal vaccine the lanolin paraffin vaccine has stronger local reaction and lower toxicity. The protecting power for guinea-pigs, protecting substance and agglutinin in the blood serum of inoculated rabbits appear later than in the normal vaccine, but their level is higher and their existence longer. In comparison with the sweet oil vaccine it has the disadvantage of having stronger local reaction and higher toxicity. It has, however, the advantage of being prepared more easily and of being superior as to protecting power for guinea-pigs, and in agglutinin and protecting substance in the serum of inoculated rabbits, while there is no substantial difference between these two vaccines in their capacity for producing complement binding substance.

Lemongrass Oil a Parasiticide.—According to Takasugi, lemongrass oil has a specific beneficial effect on skin diseases caused by animal parasites. Among volatile vegetable

oils lemongrass oil has the most toxic effect on insects. The principal toxic ingredient against insects in lemongrass oil appears to be citronella. No insects intoxicated by volatile vegetable oils beyond a certain limit can survive.

Erythrocytosis.—The number of the red blood corpuscles in Kanematsu's case was always greater than 8.2 millions, with many corpuscles slightly deformed and a hemoglobin index of about 0.65.

Congenital Malformation of Large Intestine. H. H. Gellert.—p. 911.

Intestinal Fungi in Man.—The so-called intestinal mycoses, discussed by Castellani are: (1) thrush; (2) bronchomycoses; (3) tonsillomycoses; (4) certain mycoses of the nervous system and organs of special sense; (5) certain mycoses of the urogenital system.

Query Serum in Treatment of Syphilis.—Query serum is prepared by inoculating monkeys with the filtered cultures of the organism of syphilis on bouillon. When the serum of the monkeys gives a strong positive Wassermann reaction, the animals are bled and the serum is collected and preserved in ampoules. The authors report three cases treated with Query's serum after complete failure of the recognized methods of treatment to give relief from symptoms. The relief of symptoms was marked. The cases were: (1) gummatous ulcers of the leg of long standing with hyperkeratosis and deafness; (2) tabes dorsalis with pronounced ataxic symptoms; (3) tabes dorsalis with intractable lightning pains.

Recurring Sarcoma of Ileum.—Battle's patient, a girl, aged 8, had two attacks of intussusception. At operation no tumor was found, nor did the sarcoma develop at the site of either of the attacks of intussusception. In the second attack a thickening was found, of an inflammatory character, at the apex of the intussusception, but when operation was performed five and one-half months later the growth had not increased but diminished in size. The tumor encircled the small bowel, but did not quite occlude its lumen. The mesenteric glands were enlarged over a large area. The portion of gut affected by the growth was excised and the incision carried into the mesentery so as to remove as many glands as possible, and an end-to-end anastomosis was carried out. The glands were much too numerous for a complete operation. The liver was normal. The growth was a round cell sarcoma. Coley's fluid was used for three months. There was some reaction. Another operation was done in 1916. As a resection of the growth involved division of the bowel close to the ileocecal valve, it was thought best to close both ends and join the lower end to the ileum by lateral anastomosis to the lower part of the cecum. Many glands were scattered about the mesentery. The patient was first seen in December, 1913. In March, 1920, there was no evidence of recurrence. The patient had grown considerably and enjoys good health.

Heart Block.—The main points brought out by Goodall are: (1) the relative infrequency of a rheumatic or syphilitic history; (2) the almost invariable association of the condition with mitral regurgitation; (3) the tendency to sudden death on gastric distension or exertion; (4) the occurrence of Stokes-Adams "fits" when the heart block is complete; (5) the frequency of pain as a symptom; (6) the possibility of the condition being transmitted from mother to child; (7) the ability of some patients to work or even to stand severe operations.

*Two Cases of Intramedullary Tumor of Spinal Cord; Operation. A. Feiling.—p. 957.

Novocain Anesthesia: Disadvantages from Surgical Standpoint. G. H. C. St. G. Griffiths.—p. 960.

Treatment of Tenia Imbricata Infestation.—The best routine treatment employed by Castellani for this disease is resorcin dissolved in compound tincture of benzoin (resorcin, 2 drams; compound tincture of benzoin, 1 dram). It is interesting to note that resorcin in ointment or in alcoholic solution has practically no action, and that compound tincture of benzoin alone has also practically no action, but when the resorcin is dissolved in the tincture good results are obtained.

Etiology of Pellagra.—Bigland claims that there is some evidence to show that pellagra is a syndrome which occurs most often in the underfed, using the expression in its scientific sense, and sometimes in the well fed. This syndrome may vary in character, according as the food deficiency is from without or from within. Just as perilobular cirrhosis of the liver may occur in those who have drunk spirits to excess and in those who have never had a drop of alcohol in their lives, due, as it is supposed, to some derangement of the intestine, so may pellagra occur in the underfed and in the well fed for a similar reason. In the treatment of these patients Bigland has used to good effects Fowler's solution in increasing doses, epinephrin and a liberal increase in diet.

Intracardiac Pressure and Heart Failure.—Harris points out that two factors are concerned in the production of heart failure: the condition of the heart muscle and the intracardiac pressure. A moderate intracardiac pressure acting on a damaged heart might suffice to produce heart failure. An abnormally high intracardiac pressure acting on a healthy muscle should, theoretically at any rate, also be able to induce heart failure. To remedy such an abnormal condition either of two courses is open: decrease the intracardiac pressure or strengthen the heart muscle. Heart failure must be divided into two distinct types, with a characteristic group of symptoms for each. One type is commonly met with in young people with a moderate degree of hypertrophy of the left ventricle, the arterial blood pressure, which is never unduly high with these patients, becoming lowered along with failing compensation; the heart is dilated and the pulse frequency high. The most striking feature of this type of heart failure is the normal condition of the arteries and the peripheral circulatory apparatus in general. The other type of heart failure is common in patients who show either pronounced hypertrophy of the left ventricle or sclerosis of the heart muscle with a high arterial blood pressure. The most striking feature in this form of failing heart is the sclerosis of the arteries and the general pathologic condition of the peripheral circulatory apparatus. Digitalis is indicated in cases which show the first type of heart failure. The dose can be regulated by taking as a guide the state of the intracardiac pressure. In the second type of heart failure digitalis is not indicated. In the first type of heart failure the ideal treatment is one which lowers the intracardiac pressure and at the same time leaves the arterial pressure unaltered. Caffein seems to have all the properties required. Unfortunately, many patients cannot take caffeine for any length of time on account of the nervous excitability which this drug

induces. Atropin, by increasing the pulse frequency, diminishes considerably the intracardiac pressure. It is a good plan to treat the patient alternately with caffeine and atropin. As soon as the pulse rate is considerably increased the intracardiac pressure falls proportionately. Small doses of digitalis are useful now, the drug to be continued till there is evidence of a considerable rise in intracardiac pressure.

Tumors of Spinal Cord.—The tumor in one of Feiling's cases was a psammoma of eight years' duration, the tumor in the second case was a glioma with symptoms of acute onset. The clinical course of each case is discussed in detail.

Case of Muscular Tremor (War Neurosis) Cured by Hypnotism after Three Years. H. Goodman.—p. 164.

Endothelioma of Pia-Arachnoid.—A correct diagnosis was made in Pirie's case, and appropriate palliative operative measures were followed. The diagnosis was tumor in the region of the cerebelloptine angle, probably on the left side. A decompression operation was performed. The lateral ventricles were drained at the same time. The patient survived the operation for a few days. There was a diffuse meningitis-like thickening of the pia-arachnoid due to an infiltration by endothelial cells. These were also found to have densely infiltrated several of the nerve roots, while columns of them could be traced from the pia into the brain substance, particularly the cerebellum and pons.

*Dispensary Treatment of Phthisis. What It May Achieve. H. A. Ellis.—p. 219.

Dispensary Treatment of Phthisis.—From a four years' study of tuberculosis in a county of about 125,000 people, Ellis concludes: (1) The dispensary system, properly carried out, should be the main first line of defense against tuberculosis, as being both essentially efficient and economic. (2) Sanatoriums for early cases are both valuable and necessary as a direct aid to dispensary treatment. (3) The whole question of the theories of advanced tuberculosis should be reconsidered. (4) An effort should be made to find out how much acute pulmonary tuberculosis exists (an almost incurable condition, killing usually within twelve months of first symptoms). (5) The reason for the failure of early notification should be investigated. (6) The present form of statistics should be revised; as at present published they are useless for comparison purposes.

*Relation Between Valvular Disease of Heart and Pulmonary Tuberculosis. G. T. Calthrop.—p. 263.

Relation Between Valvular Disease and Pulmonary Tuberculosis.—Calthrop has worked through the records of 1,097 postmortem examinations made at the City of London Hospital for diseases of the chest between 1889 and 1919. These represent cases of pulmonary tuberculosis and valvular disease of the heart. These 1,097 cases showed tuberculosis of the lungs or valvular disease of the heart or both; 713 showed tuberculosis only; 355 showed valvular disease only; twenty-nine showed both. The preceding histories had been as follows: rheumatic fever, five cases; rheumatic, scarlet and typhoid fevers, one case each; histories not definite for classification, twenty-one cases. The cardiac lesions were distributed as follows: mitral lesions, fifteen cases; mitral and aortic lesions, nine cases; aortic lesions only, nine cases.

Work of the American Red Cross in France.—Letulle gives a detailed account of the work accomplished by the American Red Cross in France since the United States' entry into the war. The vote expressing grateful appreciation by the Académie was mentioned in the Paris Letter, page 1339.

Influence of Calcium on Glycosuria.—Phocas ascribes to restoration of the normal balance between the sodium ions and the calcium ions the subsidence of the glycosuria on a strict milk diet. This, and the disappearance of the glycosuria, in experimental glycosuria, after injection of calcium chlorid, and other experiences of the kind, suggest that calcium salts might be preferable to sodium bicarbonate in treatment of diabetes. The nine cases he reports here seem to sustain this view. He chose lime water for the purpose, theorizing that any excess of calcium would aid in oxidation processes, instead of checking them as seems inevitable with the carbon in sodium bicarbonate.

- Prophylaxis of Tuberculosis among Children in Rennes District. Follet.—p. 319.

Treatment of Epidemic Encephalitis.—Netter comments on the analogy between this disease and epidemic poliomyelitis, although they are separate entities. Treatment along the same lines is indicated for both, that is, intraspinal injection of convalescents' serum for its specific, and hexamethylenamin for its general bactericidal action, with a fixation abscess to reenforce the natural defensive forces. However, he says, the time has not come yet for intraspinal serotherapy as the presence in the blood of antibodies neutralizing the virus has not yet been demonstrated with the encephalitis, as it has been demonstrated for poliomyelitis. Another reason is that the virus is in the nerve centers only for a brief period in poliomyelitis, while this may keep up for three months in the epidemic encephalitis, and we do not know how early it appears in the blood in the latter. He gives the hexamethylenamin by the mouth in fractionated doses in treatment of all meningitic conditions and poliomyelitis, and commends it for epidemic encephalitis although not absolutely certain of its efficacy as yet. He knows of a case in which arsphenamin treatment was tried with disastrous effect. On the other hand, jaborandi or pilocarpin seems to aid by promoting elimination of the virus through the saliva as in rabies; in 4 of his 72 cases the salivary glands were swollen, and exaggerated salivation was manifest in a number of others. He gives epinephrin with the jaborandi to counteract its depressing effect. In the 27 patients treated with injection of 1 c.c. of turpentine, an abscess developed in 19 and all these recovered except one pregnant woman. In 13 of the cases the condition was so grave that hope had been abandoned. In 14 of the 19 cases reacting with abscess production, the encephalitis was of the myoclonia type. In 25 grave cases in which no attempt had been made to induce the fixation abscess, more than 50 per cent. died. Hippocrates noted that those who escaped the "lethargus" were generally those who had developed a suppurative process, and when Fochier applied the turpentine abscess as a therapeutic measure, he explained its efficacy by its attracting the virus to the spot. Netter ascribes it to a stimulating action on the organs which provide the natural means of defense; myelocytes appear in the blood, demonstrating the participation of the bone marrow. It is probably, he remarks, by a similar mechanism that vaccines, serums and nucleinates exert their action. Another patient with extremely grave epidemic encephalitis recovered after the development of a spontaneous deep abscess in the buttock.

Rôle of Vitamins in Nutrition.—Lumière concludes from the death of pigeons fed on polished rice that they starve to death from lack of appetite, and that this is the result of stagnation of the ingested rice from lack of secretions to aid in digesting it and passing it along in the alimentary canal. The digestive and mucus glands seem to require for their physiologic functioning the stimulus from substances in the hulls of rice. The vitamins, consequently, seem to serve as stimulants for the external secretions. This conception of the rôle of the vitamins throws light on many obscure phenomena.

Syphilitic Pericarditis.—Oddo and Mattei describe a case of sudden pericarditis and asystolia in a man of 54 in the second stage of syphilis. The condition improved under neoarsphenamin, but the four injections in a little more than a month may have been a factor in the fatal pulmonary edema which developed then, about three months after the first heart symptoms. It is safer to restrict treatment to mercury in these cases.

Bulletin Médical, Paris

April 3, 1920, 34, No. 19

- *Surgical Scarlet Fever. Hutinel.—p. 323.

Surgical Scarlet Fever.—Hutinel relates that there have been 139 cases of scarlet fever in the surgical wards of the Children's Hospital at Paris in the last few years. It retards the healing of the operative wound or burn and almost invariably entails suppuration and a serious general condition. In several of the twelve cases of severe burns, the injury had resulted from mustard plasters applied to chest and back. One child had cast off the mortified tissues from such a burn when scarlet fever developed and the granulations became necrotic. The results are especially disastrous when the scarlet fever develops after an operation for hare-lip or cleft palate; the tissues become necrotic, and the operation not only is a total failure but conditions are so modified that it is more difficult to attempt it again later. Closed lesions, like fractures or tuberculous processes, escape this evil influence from the scarlet fever; it seems to be only the open lesions that suppurate. His description of the dire influence of scarlet fever as a complication of an operation suggests that no pains should be spared to ward it off. This could be accomplished by isolating the child for six or seven days before attempting a plastic operation, and continuing the isolation afterward until the wound has healed. After this has occurred the danger from intercurrent scarlet fever is materially less.

Isolated Paralysis of the Serratus Magnus.—The case reported by Villaret and his co-workers, they say, is the forty-second to be recorded. In their case the paralysis followed difficult labor in which the woman kept pulling on the head of the bed with her hands.

Epidemic Hiccup.—Dufour ascribes the persisting hiccup with fever to the prevailing epidemic of encephalitis. He knows of eight cases of the kind, and in one case the phase of hiccup was followed by myoclonia and other symptoms of epidemic encephalitis with stupor and death. In the other cases the hiccup subsided in from one to four days either spontaneously or under various measures, such as sedatives, to check the tendency to spasms, or repeated lavage of the stomach.

Isolated Congenital Dextrocardia. Laubry and Esmein.—p. 281.
*Induced Typhoid Abscesses. F. Rathery and Bonnard.—p. 285.

Gonococcemia Simulating Meningococcemia.—Bloch and Hébert report a case of febrile gonococcemia of the pseudomalarial type with arthralgia and eruption which simulated the clinical picture of meningococcemia but showed no response to antimeningococcus serotherapy. A vaccine was then prepared with the diplococcus cultivated from the blood, and immediate improvement in the above symptoms followed its subcutaneous injection. The vaccine, however, had no effect on the urethritis and epididymitis of the chronic gonorrhea.

Induced Typhoid Abscess.—In one of the two cases reported the abscess developed three weeks after an appendectomy at the site of the incision during the course of typhoid. In the other case the abscess developed at the points where turpentine had been injected in typhoid to induce a fixation abscess, twenty-seven days before, but there had been no reaction at the time. The patients were girls of about 16. In the discussion that followed this report, Widal mentioned cases of typhoid abscesses developing at the points where caffein or saline had been injected during typhoid, and related that a Paris physician had recently been summoned to court because two of his patients developed abscesses at the points where camphorated oil had been injected by a trained nurse. Netter testified on his behalf that abscesses are liable to develop notwithstanding scrupulous antisepsis.

*Traumatic Insufficiency of Aortic Valves. S. Livieratos.—p. 53.
The Leukocytosis in Typhus. G. J. Stefanopoulos.—p. 61.

Tuberculosis in Greece.—Rondopoulos cites official statistics which show a total death rate from tuberculosis during the last sixteen years in the twelve largest towns of Greece of 3.21 per thousand inhabitants. This is one seventh of the total mortality, and it has been increasing in the last few years. He ascribes this to the return of tuberculous emigrants, especially from America.

Traumatic Valvular Disease.—Livieratos reviews the literature on this subject and reports two cases in which previously healthy men of 42 and 38 after a physical effort or contusion developed symptoms of aortic insufficiency. In the younger man the traumatism was insignificant, merely stooping to pick up a pen. He perceived at once a strange sound, starting in the epigastrium and spreading, as he said, to the left ear, but there was no sense of oppression, no pain and no dyspnea or tachycardia until several months later. The aortic insufficiency became very pronounced by the end of the tenth month, completely incapacitating him. In this case the murmur was the first and for a time the only symptom of the lesion of the aortic valves. Livieratos compares these cases with those on record, including Hektoen's case.

Vascular Keratitis.—Bonnefon recalls that normally the cornea is a tissue entirely deprived of blood vessels. If blood vessels occur under pathologic conditions they may be either part of a process of attack or of defense. Scrofulous keratitis differs from phlyctenular keratitis in that the initial nodules, the phlyctenules, are absent, but instead an early vascularization indicates that the cornea is the seat of a pathologic process. This vascularization, associated with local and general symptoms of scrofula, will furnish the diagnosis. The affection left to itself progresses rapidly, with various alternations in the intensity of the painful symptoms. It ends in sclerosis if the vascularization is not arrested. This can be readily brought about, Bonnefon finds, by means of the galvanocautery.

Pathology of the Cardiovascular System and of the Kidneys.—Ribierre expatiates on the necessity for giving our patients the advantages of the newer methods of exploration, and urges group acquisition of apparatus for electrocardiography, orthodiagraphy, etc. He remarks parenthetically that in all Paris there are only two public hospitals now equipped for electrocardiography, and these owe it to the private initiative of their chief of the service. He suggests that medical societies might acquire equipment of the kind in smaller centers, accessible to the general practitioner, and appeals to the profession at large to plan to continue in some way the special laboratories and special centers which the medical department of the French army organized during the war, and which proved of such inestimable advantage. The information to be derived from the Ambard ureosecretory index is also extremely valuable, but it requires such accuracy that the findings are reliable only when entrusted to experts, another argument in favor of the diffusion of special laboratories.

Among the recent works on the pathology of the kidneys, Widal and his followers attribute all permanently high arterial blood pressure to kidney lesions. But Ribierre protests against this as too sweeping, or at least premature. High blood pressure in the forties does not always yield proof of a renal origin, not even at necropsy in cases of fatal meningeal hemorrhage. A suprarenal origin has not been demonstrated as yet, and the cases of supposed acute war nephritis sometimes proved free from any kidney lesion of appreciable kind. Such facts testify that we have much to learn yet in regard to the pathology of the kidneys.

The Third Sound of the Heart.—Lian warns that the third sound of the heart is a physiologic phenomenon, and must not be confused with the abnormal second sound with mitral stenosis.

Functional Valvular Insufficiency.—Esmein remarks that the auriculoventricular valves are more liable to become insufficient from dilatation of the ventricles than the other heart valves. Although this insufficiency theoretically would seem to aggravate the insufficiency of the heart, in reality it does not have this effect but rather lightens the work of the heart, throwing more of the task on parts less used. With extreme dilatation of the heart, digitalis may fail, and nothing but exceptionally active heart stimulants, such as ouabain will answer. He advocates giving it by the vein, saying that this should be the routine procedure with functional insufficiency developing suddenly, when digitalis is sure to fail. There is no relief here except from venesection and ouabain.

Viscosimetry of the Blood.—Josué explains that the findings are unreliable unless the blood has first been rendered incoagulable.

Angina Pectoris.—Gallavardin states that there were only 7 women among his 100 cases of angina pectoris, and only 2 of the total series were in hospital patients. About 4 per cent. of the patients were under 40, and 29 per cent. over 60. There was no reason to suspect syphilis in 63 per cent. In addition to the classic measures, he advises moderate and repeated doses of neo-arsphenamin or mercury or iodid by the

rectum on the faintest suspicion of syphilis, adding that digitalis may render useful service when symptoms of insufficiency of the left ventricle complicate the clinical picture, or theobromin, when there is renal insufficiency.

Intermittent Claudication.—Heitz expatiates on the importance of the Pachon oscillogram in estimation of intermittent claudication, and gives interpretations of its findings.

Sphygmomanometry.—Mougeot and Giroux reiterate that only repeated and prolonged records of the maximal and minimal blood pressures are instructive. A single record may prove entirely misleading.

Hemophilia.—Weil remarks that whereas formerly only 11 per cent. of the young with hemophilia lived to the age of 21, the prognosis has been transformed in late years by serum treatment. In his own practice during the last fifteen years he has not lost one of his more than fifty bleeder patients. The tendency to hemophilia is clinically and sometimes anatomically corrected by subcutaneous injection every two months of 20 c.c. of animal or human blood serum. The serum has pronounced local action, arresting hemophilic hemorrhage when gauze impregnated with serum is pressed on the bleeding wound, first cleaned of clots, etc. Transfusion of blood is likewise useful, but as the procedure has to be repeated so often, the serum should be given the preference. Nolf has reported success with repeated subcutaneous injection of 5 or 10 c.c. of a 5 per cent. solution of peptone. Weil adds in conclusion that thyroid, ovarian and suprarenal treatment, calcium chlorid and gelatin are ineffectual in familial hemophilia and should be abandoned, and he theorizes that it must be regarded as a congenital functional malformation of the elements in which the blood and the vessels originate.

Nephritis of Intestinal Origin.—Lemierre urges examination of the intestines as the first step in kidney disease of obscure origin. It is useless to treat the kidney and leave the focus in the bowel unmolested. As a rule, suppurative processes in the kidney and bladder heal quickly unless the bowel focus maintains or keeps starting them anew. If disturbances persist, concretions must be suspected. In any event, intestinal foci are peculiarly liable to breed suppuration in an already damaged kidney, so that the intestines should be supervised with special care in cases of renal lithiasis, hypertrophied prostate or stenosis of the urethra. An operation for chronic appendicitis or recurring obstruction may cure kidney lesions that had long resisted direct treatment.

The Prognosis with Chronic Nephritis.—Vallery-Radot insists that determination of the urea content of the blood should be the routine practice in examining a patient with chronic kidney disease. When this is found repeatedly to be over 1 gm. per liter, the end is not far off, within two years at most. A single test is not decisive. A patient with extreme edema and apparently doomed to a speedy death will recover and throw off the edema if the urea in the blood is below 0.5 gm. per liter, while another nephritic whose condition may seem quite satisfactory is in the terminal phase if the urea content of the blood keeps permanently above 1 gm.

Extrasystolic Arrhythmia.—Donzelot declares that hygiene rather than drugs is required for pure extrasystolic arrhythmia without visceral taint. Graduated exercise, regulation of the diet and avoidance of stimulants are all that is required; repose does actual harm. But when the extrasystolic arrhythmia occurs in persons with an already damaged heart, digitalis is indicated. With arteriosclerosis, measures to aid in elimination of waste are in order, possibly supplemented with heart tonics.

Paroxysmal Tachycardia.—Donzelot strives to remove the cause, giving ovarian or thyroid treatment as indicated, or treating goiter and stimulating the emunctories. To arrest an attack, the main point is to stimulate the pneumogastric nerve. This can be attempted by deep breathing in reclining, swallowing a big cachet, taking an emetic, compressing the vagus in the neck or compressing the eyeballs. Complete repose and a milk-vegetable diet will aid. Sedatives seldom

display any efficacy. In the protracted attacks, almost all that can be done is to watch over the heart and give heart stimulants at the first sign of weakening. If the attack has lasted several days, it is better to give digitalis without waiting for signs of weakening. When called late in the attack, injection of ouabain by the vein should be considered, not over 0.25 mg., doubling the dose the next and the following day at need.

Paroxysmal Hemoglobinuria.—Giroux agrees with those who think that paroxysmal hemoglobinuria is a kind of auto-anaphylaxis. The success of reinjecting the patient with his own serum seems to sustain this assumption. These injections do no harm, and have most effectually warded off return of the attacks. Specific treatment for syphilis has proved effectual in other cases. The only indications in the attack itself are to keep the patient warm in bed.

Present Status of Lethargic Encephalitis. P. Blum.—p. 237.

*Sporotrichosis of the Genital Organs. A. Brainos.—p. 247.

*Fibrous Tumors of the Palm. R. Ducastaing.—p. 248.

Unrecognized Sporotrichosis of the Genital Organs.—Brainos reports two cases because of the unusual localization of the disease in the genitals. The first patient was admitted to the service in October, 1918, with the diagnosis "syphilitic chancre of the penis." He presented on the body of the penis, in the dorsal region, an ulcerous wound about the size of a dime, which was not indurated at the base; no inguinal adenitis. The Bordet-Wassermann reaction was negative; nevertheless, treatment as for syphilis was tried, but without success. The ulcer took on a phagedenic appearance and the patient was much discouraged. Brainos suspected the presence of sporotrichosis, and bacteriologic examination of the pus confirmed his suspicions. Potassium iodid, following the Gougerot method, changed the clinical picture remarkably within a few hours. At the end of a month the ulcers had healed over completely. After a two weeks' interval there was a recurrence of the sporotrichosis in the same region, which was quickly checked by potassium iodid. As a matter of precaution the patient was given treatment for two weeks at a time for three months. He remained in the hospital until April 8, 1919, up to which time there had been no further recurrence. Brainos remarks that if in giving antisyphilitic treatment he had happened to add potassium iodid, a cure would have doubtless been effected, and the false diagnosis of syphilitic gumma would have been confirmed. Therefore, he recommends that when a physician institutes tentative antisyphilitic treatment for a local lesion, the specific nature of which has not been confirmed bacteriologically or clinically, he should avoid using potassium iodid with mercury or arsenical remedies.

Fibrous Tumors of the Palm of the Hand.—Ducastaing reports three cases in which fibrous nodules had developed insidiously without any known trauma, either of an accidental or industrial nature. There was no frank history of tuberculosis, but there was of arthritis, which bordered on the type of tuberculous rheumatism. The numerous newly formed vessels were the seat of an endovascular inflammation of the type described by Poncet. The centers of the tumors were infiltrated with hemoglobin granules. All the intermediary stages of the slow development could be seen at one time.

*Clinical Shock. F. Vidal, P. Abrami and E. Brissaud.—p. 181.

Hemolysis in Clinical Shock.—Vidal and his co-workers in this long study of certain phenomena in shock explain the nature of the numerous and widely diverse clinical manifestations—from the accidents of anaphylactic order, the disturbances from parenteral injection of colloidal and crystalloid substances, and the spontaneous syndromes of infectious order, such as certain attacks of high fever, to the humoral derangements, as in paroxysmal hemoglobinuria—all are traceable to a single mechanism, the same process

of destruction of colloids, a colloidoclasia. In this new field of colloidoclasia we may soon discover many other instances of phenomena due to upset of the colloidal balance. Perhaps certain symptoms hitherto ascribed to intoxication may be the expression of a sudden loss of colloidal balance. True intoxication acts by a chemical process; it alters the molecules and may destroy them, but shock, they reiterate, is merely an upset of the physical balance between colloidal structures. The most convincing testimony of this, they say, is the one phenomenon common to all the above manifestations of shock, namely, the sudden destruction or dissolution of erythrocytes, the *crise hémoclasique*. When we see an attack of asthma, of urticaria, of hemoglobinuria, we can always find the paroxysm of hemoclasia if we seek for it. The direct disturbances from it are so slight that they escape attention, but it is another instance of the importance of this occult symptomatology, inaccessible to our ordinary means of investigation. The natural or acquired susceptibility of certain groups of cells will determine the organic localization of the colloidoclasia. This links colloidoclasia with idiosyncrasies. Crystalloid substances do not seem to be able to induce shock unless they get into the blood suddenly and in large amounts (arsphenamin, sodium chlorid and bicarbonate), and the shock can be warded off by preliminary injection of a minute dose of the same. The phenomena in paroxysmal hemoglobinuria from chilling show that this is an auto-anaphylaxis from the cold, without the intervention of any foreign colloidal or crystalloid substance.

Burns.—Roziés remarks on the good results in severe burns from normal horse serum, the hot air jet, and phototherapy, but the film method has won most adherents. The paraffin or wax mixture is within the reach of everyone. He has had good results also with a waxed tulle which does not stick to the tissues. It is dipped in a mixture of petrolatum, wax, castor oil and balsam of Peru, with a melting point at 30 C. Bernhard published as long ago as 1904 his success in treating extensive burns with heliotherapy, and Aimes reported in 1913 the excellent results from it in a recent burn and in an old case in which the extensive burn of the third degree was healing only sluggishly, but it healed over smoothly under thirty-five sunbaths by the regular heliotherapy technic.

*Mastoiditis and Suboccipital Pott's Disease. G. Portmann.—p. 916.
Conc'n.
Complications of Knee Sprain. Thévenet.—p. 942.

Tuberculous Ovarian Cysts.—Forgue and Chauvin were able to collect from the literature only thirty-five cases, the oldest case being that of Spencer Wells, reported in 1863. Many cases reported as such cannot be definitely so regarded as there was no histologic control, or the localization of the process was not sufficiently fixed. Tuberculous ovarian cysts are found in three forms: (1) tubo-ovarian with tuberculosis of the common cavity; (2) external, superficial tuberculosis associated most frequently with peritoneal tuberculosis, and (3) deep tuberculosis. This form of tuberculosis is practically never primary but develops following another focus of infection, found in the majority of cases in the peritoneum or tube.

Mastoiditis and Suboccipital Pott's Disease.—Portmann states that since the treatment of mastoiditis and of Pott's disease are so widely different, diagnostic errors in this field are exceedingly serious and result in dire consequences to the patient. He discusses in detail the more important symptoms of the two diseases which aid in establishing a diagnosis. If there is no cervical abscess, the pains in suboccipital Pott's disease are accentuated by the various movements of the head, in mastoiditis by pressure in the region of the antrum. In Pott's disease there are no morphologic changes of the mastoid region, as with mastoiditis; in the former there is early and marked stiffness of the head and neck; in mastoiditis if this exists at all it is not pronounced; in Pott's disease there are no ear symptoms, as in mastoiditis. In Pott's disease the general condition is rather bad, and often there are infectious lesions of other organs. In the presence of a cervical abscess, the pain in the region of the abscess is slight in Pott's disease, but severe in meningitis; in the former the abscess is regular, not inflamed, without peripheral edema; in mastoiditis the abscess is not sharply defined, has peripheral infiltration and inflammatory reaction. In Pott's disease puncture of the abscess releases a thin serous, lumpy pus which may contain tubercle bacilli; in mastoiditis the pus will be phlegmonous, thick and of uniform consistency, with no evidence of tuberculosis. Fistulas if present will in Pott's disease show purplish disconnected borders, with occasional fungosities, and will emit a pus not uniform in consistency; in mastoiditis the borders will be regular, red and will emit a phlegmonous pus. Roentgenoscopy will disclose lesions of the cervical vertebrae in Pott's disease, but none in mastoiditis; in the former a probe introduced in the fistulous tract will point toward the cervical column, in mastoiditis toward the mastoid.

- *Direct Resuscitation of the Heart. K. Henschen.—p. 261.
Influenza and Tuberculosis. F. Deiss.—p. 268.
Lethargic Encephalitis. W. Kauffmann Ernst.—p. 270.

Resuscitation of the Heart.—Henschen relates that he is one of the few who have succeeded in permanently resuscitating the heart, after complete arrest, by direct injection of a stimulant into the heart. Van den Velden revived the heart in 13 of his 45 cases; Hesse in 4 of his 6, and Volkmann and Heilmann in 14 of 17. But in these groups the revived heart action gradually subsided anew in from twenty minutes to ten hours at most. Henschen reviews the history of efforts in this line, simple injection of a stimulant into the pericardium, ventricle or right auricle, with or without infusion of a fluid to give the heart enough to pump on, and with or without preceding release of blood from the heart to reduce the tension, a central venesection, as it were. The infusion can be made only in the left ventricle, and Fick says that the ventricle can hold only from 50 to 75 gm. Zuntz places the limit at 60 gm. Henschen gives several illustrations showing the danger zones to be avoided, especially the wall separating the auricles from the ventricles, the zone of the His-Tawara bundle, the upper third of the anterior longitudinal groove, the base of the heart near the mouth of the vena cava (region of the sino-auricular system), and the lower half of the atrioventricular boundary zone. He describes in detail four cases in which he has applied these resuscitation measures, once after collapse of the heart from hemorrhage from a gastric ulcer. He injected 1 c.c. of epinephrin and 0.5 c.c. of a pituitary preparation into the left ventricle a few minutes after the heart had stopped beating. The heart and pulse began to beat strongly again at once but gradually dropped again as spontaneous

respiration could not be induced during forty-five minutes of artificial respiration. In another case the intracardial injection was made by mistake in the anterior interventricular vein, instead of in the ventricle itself, and the striking benefit lasted only for fifteen minutes. His third case was a bullet wound of the heart, and the heart was revived to strong and regular action by the injection of 1 c.c. of 1:1,000 epinephrin and half this amount of the pituitary preparation. The young man was convalescing smoothly when fulminant pericarditis proved fatal the second day. The one permanently successful case

1-2. Puncture to relieve right auricle.
3-4. Puncture to relieve right ventricle.
5-6. Points for infusion of left ventricle.
A, aortic valve; B, tricuspid valve; C, pulmonary valve; D, bicuspid valve.

was a man of 32 who was rendered unconscious by a beer keg falling on his chest and upper abdomen. It was impossible to tell whether the condition was from intense pleuroperitoneal traumatic shock or from internal hemorrhage. The heart stopped beating during the exploratory laparotomy, and massage failed to revive it. Then 1.5 c.c. of the epinephrin solution was injected in the pericardium through the fourth left interspace, inside of the mammillary line, at a depth of about 2 cm. At once the flabby, pulseless heart grew taut and began to beat strongly and regularly, and signs of life became apparent. Then 700 c.c. of physiologic saline with 10 drops of epinephrin and 5 drops of the pituitary were infused in the arm and recovery was soon complete.

Elimination of Chlorids in Febrile Diseases. G. Marcialis.—p. 86.
To be cont'd.

Atypical Meningococcus Infection.—Bolaffi has encountered cases of meningococcus meningitis with an onset simulating measles; others in which the lumbar puncture fluid showed merely lymphocytosis and the disease progressed with extreme cachexia. One little girl died the sixty-seventh day, the child looking like a little mummy. The case teaches the importance of repeating puncture of the spinal cavity at different points to reveal meningococci; everything seemed to point to tuberculous meningitis until too late for serotherapy to be effectual. The meningococcus nature should be suspected when days of apyrexia are interrupted by periods of high fever and there is rapid loss of weight. The search for tubercle bacilli or meningococci in the spinal fluid should be kept up, and the centrifugate sown on culture mediums favorable for the meningococcus. The ophthalmoscope may reveal tubercles on the choroid. When the meningococcus meningitis has passed into a chronic phase, it is almost certain to be mistaken for tuberculous meningitis. In one soldier the meningococcus induced acute fatal septicemia and purpura, but necropsy failed to reveal any signs of meningitis. In other cases the onset suggested typhoid until, about the tenth day, purpura developed. The much enlarged spleen in such cases may be due to unsuspected malaria. In another case rheumatic polyneuritis was diagnosed from the symptoms until the end of the second week. Deafness from the first was finally explained by the discovery of the meningococcus. In another case intense pain in one ear and pains in the limbs, with slight fever, were the only symptoms, for three days. One child had presented merely slight fever and extremely slight pain when

the head was bent; otherwise she seemed entirely well, and Bolaffi did not venture to inject the antiserum on these findings alone, but eight hours later other symptoms cleared up the diagnosis. Investigation of the mode of onset is usually most instructive for the differential diagnosis.

Epidemic Encephalitis. P. Boveri.—p. 228.
*The Brain and the Genetic Function. V. Desogus.—p. 233.

The Brain and the Genetic Function.—Desogus compares with Ceni's experimental findings Forster's recent study of the ovaries in 100 insane women and Todde's study of the testicles in 200 insane men and in thirty others who had been killed accidentally or had died from acute disease. All the data testify to a close connection between mental disease or trauma of the brain and the condition and functioning of the sexual organs. Mj  n's recent research on the relations between alcohol and generation has convinced him that the deleterious influence of alcohol on the organs of reproduction is not direct but through the superior nerve centers. Todde has emphasized the pronounced difference in the testicles of the insane and those of the noninsane dying from a similar cause, such as tuberculosis. Stieve reported in 1918 the extreme involution evident in the ovaries of hens kept in close captivity, in comparison to other hens. He ascribed this to the psychic influence of the confinement. None of the other internal organs showed appreciable change during the captivity. Ceni's conclusions from his more than thirteen years of experimental research and clinical observation are to the effect that the biologic processes which constitute the phenomenon of procreation are under the control of nervous influences which are more and more complicated the higher in the animal scale. In the lower vertebrates the spinal cord alone is involved, while in the higher vertebrates the spinal cord controls merely the trophic processes and loses more and more of the control, which is assumed by certain brain centers. These brain centers function under the direct stimulus of psychic forces which, by their insufficiency or by their excess, may entail degeneration and hence sterility. An excess of psychic stimuli may excite or depress according to the individual reaction.

*Extract of Bran in Infant Feeding. Fernandes Figueira (Rio de Janeiro).—p. 65.
*Azurophilia in the Blood in Measles. A. F. Canelli.—p. 82.
*Treatment of Meningococcus Meningitis. I. Malvani.—p. 88.

Extract of Bran in Infant Feeding.—Fernandes discusses the literature on deficiency disturbances, describing much experimental research and clinical experience of his own. Everything seems to indicate, he remarks in conclusion, that the continuous preponderance of any bacterial flora is injurious for an infant, even with breast feeding, kept up for more than a year without anything else being given. By the end of the twelve-month a deficiency in mineral reserves becomes apparent. The addition merely of a vege-

table soup or a little starch works surprising changes in the infant. He gives precipitated calcium phosphate in certain dyspeptic conditions from intolerance for carbohydrates, and this phosphate, as well as casein of which it is a constituent, produce excellent effects. Even when the diet seems admirable, it is indispensable to vary the food from time to time to stimulate and modify the mechanism of assimilation. This is the explanation of the benefit from the extract of bran. Large amounts, up to 5 or 6 gm. daily, cause diarrhea. But with only 2 or 3 gm. the infant's stools keep normal and it increases promptly in weight. This increase in weight does not keep up, however, if the extract of bran is continued. If it is dropped for two or three weeks and then resumed, the weight shows another rapid gain. It seems to interrupt the exclusive predominance of a certain bacterial flora.

Azurophilia in the Blood in Measles.—Canelli examined the blood of 60 infants and young children and 5 soldiers, all with measles, and in 33 persons with other diseases, seeking for cells containing azurophil granulations. This is not a specific finding with measles, as it is found in pneumonia, scarlet fever, etc., but the azurophilia is so frequent in measles and so pronounced, that it may well serve as an aid in the differential diagnosis. The azurophilia reaches its height with the eruption phase. Azurophilia is exceptional under other conditions, as Canelli noted in examining blood specimens from 5,200 soldiers with malaria and 10,000 other malarial subjects.

Treatment of Meningococcus Meningitis in Children.—Malvani relates that success beyond all anticipations has been realized at the children's clinic at Florence in treatment of meningococcus meningitis with a vaccine to supplement serotherapy. Its value was most evident in the grave cases that dragged along without tendency to spontaneous healing under serotherapy. By the vaccine treatment the infection was attenuated to a degree which permitted the natural defensive forces to gain the upper hand. The meningococcus changes its biologic behavior in different epidemics so that it is important to use the local strains in preparing the antiserum, and as many different ones as possible. Capogrossi's success in two grave cases with intraspinal autoserotherapy justifies this technic when fear of anaphylaxis prevents the use of other serums. In infants the meningitic process is peculiarly liable to become walled off by obstruction of the communication between the skull and the spinal cavity. When only a small amount of fluid can be obtained by lumbar puncture, while the symptoms keep serious, it is a simple matter to puncture the ventricle through the anterior fontanel. For older children it is necessary to trephine.

 *Perforation of the Retina. J. de Jesús González.—p. 126.
 Hygiene of the Home. J. E. Monjarás.—p. 133.

Vertigo and Syncope in Relation to the Nervous System.—Loaeza reports a puzzling case of repeated and alarming syncope in a man of 80 which he finally differentiated by exclusion as hysteric syncope, and cured by suggestion. He contrasts the clinical picture with syncope and severe vertigo of central or peripheral origin.

Morphin in Obstetrics.—Bulman emphasizes the dangers from the use of morphin in obstetric cases, especially the danger for the child. In the discussion that followed his remarks, Montañó told of being called to a case in which the physician had given an intraspinal injection of cocaine to relieve the labor pains, and the woman succumbed to hemorrhage from inertia of the uterus.

Perforation of the Retina.—De Jesús gives an illustrated description of the findings in the retina which had apparently been perforated at the fovea centralis from a contusion in childhood. Since then the visual acuity of that eye had been less. The pear-shaped foramen is the size of two thirds of the papilla, but the vessels in the retina seem to be normal. He compares this case with the seventy-nine others he has found in the records, with a history of known trauma in 81.8 per cent. It is the second case published in Mexico.

- *Alcoholism and General Paresis. J. Sanchis Banús.—p. 65.
 *Diabetes Insipidus. J. Madinaveitia.—p. 71.

Alcoholism and General Paresis.—Sanchis reiterates that the symptoms of chronic alcoholism may simulate absolutely the clinical picture of general paresis, and both alcohol and syphilis are frequently found in the antecedents of each. He gives the details of two cases in which only lumbar puncture gave the clue, confirming in one case the assumption of general paresis from the comparatively few hallucinations, and the delirium of the megalomania type. In the other case, as the alcoholic psychopathy subsided, the mind became clear. The wealth of hallucinations also testified to the alcoholic origin.

Diabetes Insipidus.—Madinaveitia comments on Marañón's recent statements as to the share of the pituitary in the production of diabetes insipidus, and the fact that pituitary disease is not always accompanied by diabetes insipidus. There is some reason to believe that the pituitary tumor may compress the center regulating osmosis, while the lack of the normal pituitary hormone may further contribute to upset the osmotic balance.

Immunization Processes in Trichophytosis in Man.—Blumenthal and von Haupt state that in deep trichophytosis, in the majority of cases, antibodies may be shown to be present in the blood serum, while in superficial trichophytosis, this is the exception. In general, the quantity of antibodies is directly proportional to the severity of the clinical phenomena. Part of the therapeutic effect of trichophytin injections is doubtless due to stimulation of the production of antibodies. The allergic reaction takes place also in cases of nonparasitic sycosis and with tuberculous glands. A strict cell immunity, which would presuppose that trichophytosis occupied a special position among infectious diseases cannot be established. Their conclusions are based on study of thirteen cases of ringworm and ninety-one of deep trichophytosis.

Comparative Pathology of Melanotic Tumors.—Lubarsch recalls that comparative histology shows that the melanotic pigment occurs in two different kinds of cells, namely, in the epidermis cells of the skin and in epithelial cells, especially of the organs of sense, and also in the chromatophores, found in the connective tissue and among the epithelial cells. As for the origin and character of the pigment, chemical investigations have shown more and more clearly that the

formation of the pigment is connected with the decomposition of albumin. The high sulphur content of melanin is an indication of such origin. As for the starting points of melanotic tumors, Lubarsch is inclined to the view that melanocytoblastomas arise primarily only where melanocytes and melanoblasts occur normally or at points to which such cells have been carried by some abnormal developmental process. In the last thirteen years melanotic tumors formed 0.89 per cent. of the 2,274 malignant tumors found in 18,113 cadavers. In Folger's statistics, they formed 42.88 per cent. of the 527 cancers found in 175,745 horses and 0.35 per cent. of the 865 cancers found in 143,309 dogs.

Physical Factors in Treatment of Empyema.—Moszkowicz discusses the advantages and disadvantages of Bülow siphon drainage, rib resection, and the Revilliod suction treatment in empyema, and then recommends what he calls the combined suction and lavage treatment. He has used the method for many years and states that it gave good results during the last influenza epidemic. Of twenty-one patients operated on in this manner he lost four, but necropsy revealed complications such as multiple abscesses, pericarditis and diffuse involvement of both lungs. Under local anesthesia he resects in the posterior axillary line about 2 cm. of the sixth rib and then inserts two drains, instead of one, in an opening in the pleura just barely large enough to receive them. The first drain just enters the pleural cavity, the second goes in a little deeper. Both drains are embedded liquid-tight in the latissimus dorsi by means of catgut sutures, and the skin is sutured tight around them. The ends of the tubes (50 to 60 cm. long) rest in glass receptacles containing a solution of salicylic acid. As very little air has penetrated the thorax, siphon drainage begins at once. The shock is minimal, and after most of the pus has thus drained out, the patient breathes easier. One bottle is then filled with warm physiologic sodium chloride solution and is raised to a plane from 10 to 20 cm. above the thorax. The fluid from this enters the wound and flows off, mixed with pus, through the other drain. It is Moszkowicz's experience that the warm lavage is agreeable to the patients, and breathing becomes easier. There are some contraindications for lavage such as the existence of a communication between the pleura and the bronchi. Moszkowicz emphasizes the importance of breathing exercises in order to restore the lung to its normal condition, and for this purpose has found the hints contained in Hofbauer's "Summ- und Fächerübungen," *Deutsche medizinische Wochenschrift*, 1916, p. 125, of great value. He also stresses that the presence of pus as shown by the exploratory puncture may not be an absolute indication of a "free" empyema requiring an operation. The condition may be due to interlobar empyema or an abscess which will require intervention at an entirely different site. As a last word, too great attention cannot be given to after-treatment, especially from the standpoint of intrathoracic pressure.

Case of Barbitol Poisoning.—Moszeik reports that, July 22, a nurse, aged 25, was admitted to the hospital in stupor. Circumstances indicated barbitol poisoning. Following

stomach lavage the patient was given coffee to drink and caffeine subcutaneously. She then slept for forty-eight hours continuously, during which period she did not react to external irritants. July 25, she opened her eyes when her name was called, but closed them again at once and fell asleep. July 26, she noticed for the first time that some one was standing at her bedside. Recovery was now rapid, though a certain lassitude persisted for some time, and the muscles of the lower extremities seemed fatigued. The patient had taken 7 gm. of barbitol with suicidal intent. The drug had taken effect within five minutes, the patient stated. There was no nausea and no vomiting. Menstruation, begun on the 22d, was not affected.

A Nonspecific Provocative Method in Urethral Gonorrhea.

—Müller recommends the use of a nonspecific method of provocation in the diagnosis of etiologically uncertain affections of the lower urinary passages and in chronic disease of the genital organs in man. He uses an albumin (from milk) solution as described in detail in *Medizinische Klinik*, 1918, p. 688. The method of injection is as follows: The extensor aspect of the forearm is cleansed with benzine; a fold of the skin is gently raised, and the injection is made parallel with the surface in such a manner that the tip of the syringe keeps within the epidermis. From 0.2 to 0.3 c.c. of the albumin solution is injected, whereupon a white wheal arises. Two such wheals suffice for a single treatment. If no wheal appears it is a sign that the injection was subcutaneous instead of intracutaneous, and the injection should therefore be repeated. After such intracutaneous injections, moderate increases in the blood leukocytes appear but with no difference between cured gonorrhea and a still active infection. In about six hours a slight itching sensation occurs in the urethra; following which there is a marked increase in the discharge. If the discharge is examined for two days successively, the gonococcus can be almost certainly isolated if gonorrhea is still present. This judgment is based on experience with over 1,500 cases in the Hamburg Marine Hospital. Of the patients who gave a negative test by this method less than 1 per cent. were shown later by other methods to be infected. Müller finds the above described method much superior to the usual provocative methods by which specific antigens are introduced into the organism, for it does away with the otherwise inevitable injury to the already diseased mucosa.

Tumors of the Urinary Apparatus in Chemical Workers.

These tumors, Oppenheimer states, deserve especial attention for several reasons, not so much on account of their severity and relative frequency, but because the manner and the process of their development can be studied with the same degree of certainty as if they were produced experimentally. In the present state of our knowledge we are unable to detect any difference histologically and clinically between industrial tumors so-called, and those that arise under ordinary conditions. Therefore, any deductions that can be made in regard to industrial tumors are probably applicable, to a certain extent at least, to tumors in general. From 1910 to 1919 twenty tumors of the urogenital apparatus were studied. These tumors were all plainly traceable to the action of chemical agents. Certain substances (benzidine, anilin and anilin dyes, etc.) produce tumors of the urinary passages, more especially of the bladder. The process of development extended over a long period of years. The interval between the beginning of the harmful occupation and the first appearance of symptoms ranged from nine and

a half to twenty-eight years. After a change of occupation tumors developed in two cases ten and seventeen years later, proving that though the external cause was removed the disease had continued to develop. A long latent stage precedes the appearance of the first local or general symptoms. Different substances may produce tumors of the same type, and the same substance may produce tumors of different types. Duration and intensity of the exposure to the injurious substance could not be shown to have any influence on the process of development; nor did duration and intensity affect the type of tumor, as far as could be discovered. The prognosis for the carcinomas acquired in chemical industries is unfavorable, and for the papillomas at least dubious.

*Thrombosis of the Longitudinal Sinus in Influenza. B. Szigeti.—p. 291.

Thrombosis of the Longitudinal Sinus in Influenza.—On account of its rarity, Szigeti reports a case of this kind in an adult. The patient was admitted, Feb. 8, 1920. The disease took a stormy course and the patient died, Feb. 12, 1920. An acute delirium set in soon after admission. As the disease progressed there were epileptiform attacks, during one of which the patient succumbed. A diagnosis of influenzal pneumonia was made, although the physical signs were slight and there was no expectoration, for during this influenza epidemic severe anatomic lung changes were often associated with quite insignificant objective phenomena. The thrombosis was not suspected from the clinical evidence but was revealed at necropsy. In a search through the literature Szigeti found only one similar case, that of Leichtenstern, who, however, was not absolutely convinced that influenza was present in his case.

Hydrocyanic Acid in Extermination of Vermin.—Lubsen, Saltet and Wolff state that their extensive experimental and practical experience confirms the extreme efficacy of hydrocyanic acid in extermination of rats, insects, moths, mites, etc., while it does not affect clothing or metals or foods, except milk and other fluids. It can be used to kill destructive insects in tobacco, flour and other foodstuffs. They found that the gas masks used by the British army are effectual in protecting against this gas; only after as much as 20 l. had been passed through the mask, some of it failed to be retained by the chemicals in the mask. The Netherlands and the German gas masks are no protection against HCN. They recommend using the gas in the evening and leaving the room shut up over night, airing it out in the morning. When this is not practicable, the gas can be used early in the day and the room be ready to use again at night, but mattresses, etc., must be aired and beaten out of doors to get rid of the gas. They advise letting the wind blow through the adjoining rooms or flats while the gas is being applied, thus interposing a zone of safety between the gas filled rooms and the inhabited rooms beyond. Two persons should be supplied with masks so that in case of accident one can care for the other. Nothing has been found to date effectual in combating the poisoning from the gas beyond artificial respiration and stimulants. Injection of sodium thiosulphate, which has been theoretically advocated, would require doses beyond what could be used in man. In their experiments the only living thing that resisted the action of the gas was the weevil. This seemed to be able to hold its breath and could thus resist high concentrations of the gas. But there are other effectual means of combating this.

*Urobilinuria with Cholelithiasis. S. Hansen.—p. 415.
*Stenosis of Lacrimal Passages. N. R. Blegvad.—p. 423.
Necessity for Systematic Neurologic Examination of Syphilitics. C. Rasch and H. J. Schou.—p. 428.

Urobilinuria with Cholelithiasis.—Hansen found urobilinuria in 80 per cent. of fifty persons with cholelithiasis and in 100 per cent. of the thirty-three examined during gallstone colic, while the findings were negative in 71 per cent. of 175 control cases. The mere presence of gallstones is not enough to induce urobilinuria, but the latter is constant during an attack of gallstone colic if the common bile duct is permeable. If the gallstone has obstructed the common bile duct so that no bile is able to pass into the bowel, then bile pigment may be found in the urine, but no urobilin. In some of the cases which seemed to be gallstone colic, but no urobilin was found in the urine, the reliability of this test was confirmed by the operation which disclosed duodenal ulcer, cancer of the liver or other lesion but no gallstones. Of course urobilinuria is not a specific reaction to cholelithiasis, but it is proving, in connection with other findings, a very valuable aid in the diagnosis and in the estimation of the course of the case with gallstones. He theorizes to explain why gallstone colic is accompanied by this abnormal elimination of urobilin in the urine, ascribing it to relative insufficiency, a flooding of the liver with urobilin. One of his charts shows urobilinuria of 1:40, then 1:80 the first and second days of the attack, and then a gradual decline the four following days to zero. If the urine had not been tested till the fourth or fifth day the urobilinuria would have escaped detection. His tests showed further that fever in itself does not induce urobilinuria. His improved technic for estimation of the urobilin content of the urine was described in THE JOURNAL, March 23, 1918, p. 896. He says it is far more sensitive than the Schlesinger reaction. The latter is positive when the response is within normal range.

Operative Treatment of Disease of the Lacrimal Apparatus.—Blegvad lauds West's operation for dacryocystorhinostomy, but has modified the original technic by using an electric motor to cut away the bone and median wall of the lacrimal sac. This much simplifies the West operation, and proved very successful in his seventeen cases.

Manometer for the Spinal Fluid. N. R. Christoffersen.—p. 449.
The "Twilight Sleep" in Obstetrics. A. G. Lauritzen.—p. 454.
Tapeworm. H. R. Magnus.—p. 462.

Celsus' Kerion.—Rasch comments on the rapid cure of deep trichophytosis which is in such contrast to the prolonged course of the more superficial forms. He ascribes it to the complete transformation of the organism in the former, leading to the production of antibodies. In his 109 cases in a recent seven years there were 2 cases in children in which the trichophytosis of the scalp and body was accompanied by an eruption apparently identical with that of scarlet fever. These 2 cases formed about 4 per cent. of his 51 cases of Celsus' kerion. In some other cases the kerion was followed by what seemed to be erythema nodosum. He treated the kerion only with compresses with boiled water, changed four or six times a day, and was impressed with the absence of staphylococcus secondary infections. There seemed to be a temporary immunity to staphylococci. Under this compress treatment the trichophytosis disappeared in the course of from three to six weeks; the localizations elsewhere vanished at the same time, and no new lesions developed. This not only confirms the production of antibodies which clear the system of the causal agent, but it suggests the possibility of utilizing this curative potency of Celsus' kerion in treatment of other forms of trichophytosis which resist all measures for months and years (*T. violaceum*, for instance). Inoculation with kerion might transform conditions and clear the system of the whole. Sabouraud suggested ten years ago that kerion might vaccinate against tinea, but Rasch does not know that this suggestion has ever been applied in practice. He regards it as rational and justified to give it a trial in an appropriate case.

DEFICIENCIES IN OUR METHODS FOR THE TREATMENT OF CHRONIC NEPHRITIS

NEED FOR INVESTIGATION *

HENRY A. CHRISTIAN, M.D.
BOSTON

In considering the best methods for the treatment of chronic nephritis (Bright's disease) we labor under the disadvantage of dealing with a disease regarding which there are many gaps in our knowledge. Of its etiology we know surprisingly little in any exact sense, though the view is receiving increasing support that many of the cases have their primal cause in an infection of bacterial nature, most frequently of the streptococcus group. Even granted, however, that organisms of the streptococcus group originate the renal disturbance, we are not helped much in the matter of treatment, because, in case of the known nonrenal streptococcus lesions, we are able to treat only by elimination or drainage of a focus of infection, and can do little, if anything, toward counteracting the toxic substances that are produced and distributed to the body organs. If actually resulting from an infection, the chronic renal lesion presents itself months or years afterward, too late to be helped much by removal of the focus of infection even if still present. In other words, in the earlier, easily treated stages of the infection, the infection may pass unrecognized; or, what happens more frequently, there is nothing to indicate the beginning of a lesion in the kidney which slowly and gradually will develop into a recognizable nephritis. In the later stages when the renal lesion is easily recognized, the focus is no longer existent, or if present, its removal can change but little the renal damage already done. I have been very much struck, in my own experience, with the relatively few cases of chronic nephritis that seem to have been a direct sequence to a demonstrated infection or infectious disease; most of these have belonged to a rather distinctive group of cases, progressing rapidly to a fatal issue and perhaps better thought of as subacute than chronic nephritis. In these none of the methods of treatment seem to have had the slightest effect on the course of the disease; that is to say, knowledge of a close association with an infection, so far, in this group, has not shown the way to a successful treatment.

As to the actual type of lesion developing in the kidney, we know very little while the disease is progressing. Clinical classification cannot be accurately

correlated with structural classification, and there are so many gaps in our knowledge of the pathologic lesion in the kidney, particularly in regard to its histogenesis and its effect on function, that a structural consideration of renal lesions helps but little in treatment. During life, anatomic diagnosis in any narrow sense is almost impossible and even when successfully made helps but little in treatment.

In many of the patients with chronic nephritis there are coincident vascular lesions, in the main of degenerative nature; but of these we know as little as of the renal disturbances, so that their presence merely handicaps us all the more in applying a rational treatment.

In recent years, much attention has been given to the study of renal function in nephritis, and we have learned many facts in regard to it. The question naturally arises: How much has this newer knowledge of renal function aided us toward a more satisfactory method of treating these patients?

Except for the removal of recognized foci of infection and as prompt and efficient treatment as is possible of all acute infections, we at present can do practically nothing for the prevention of nephritis. Preventive treatment in a practical sense is almost nil for chronic nephritis, and will remain so until we learn more of the etiology and particularly of the factors that influence the progressive development of renal lesions.

THE AIMS IN THE TREATMENT OF CHRONIC NEPHRITIS

As we treat the chronic nephritic today, we aim (1) to stay the progress of the lesion; (2) to remove edema if present to an annoying degree, and (3) to prevent the formation and combat the effects of toxic substances, the result of the presence of the renal lesion. Let us briefly take stock of these methods and the knowledge on which they are founded.

1. *To Stay the Progress of the Lesion.*—With this in view we make two points of attack: (a) We remove foci of infection and guard against repetition of infections, and (b) we attempt to give the renal tissue as much of a chance as possible for recuperation by reducing its work, largely by limitations of diet.

(a) As already intimated, frequently we discover no focus of infection; and when we find one its removal usually accomplishes little, for the damage to the kidney has been done and we do not know how to increase renal repair. Yet it remains rational to seek for and remove, so far as is possible, foci of infection when found; we must not, however, promise the patient any striking result from such treatment, though occasionally great improvement may result. To guard against repetitions of infection, we urge the avoidance of exposure to contagious diseases and the reduction of contacts with infection. For a better

* Read before the Section on Pharmacology and Therapeutics at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

resistance we urge the best possible hygiene, but these are all very general directions in very general terms; they are easy to state in a general way but difficult to carry out.

(b) To decrease renal work we limit diet. The kidney is an excretory organ concerned in the elimination from the body of water, salts, and nitrogenous and other substances; some well understood, others, such as various toxic substances believed to be eliminated by the kidneys, little understood. We assume that by limiting the intake of food and fluid we decrease the work of the kidney and give the kidney physiologic rest and so opportunity for repair. The tendency today is to decrease fluid intake, especially water. What is the basis for this? We have evidence that water excretion causes renal work, and to an injured kidney an increased fluid intake can lead to a decreased output of urine. When edema is present, we can see it increase as fluid intake increases. We also know that there is a limit to the reduction of water intake below which it is injurious to go because of the concentration of other substances to be excreted which is incident to great water restriction. Very likely, too, a much decreased fluid intake will cause injury to renal cells. Consequently, it seems reasonable to assume that there is an optimum mean of water intake. Do we really know this mean? I think not, except in the sense of the effect of fluid limitations over rather short periods; and even here, knowledge is imperfect. There has been surprisingly little critical study of the effects of different water intakes, especially over long periods of time. What we need to know is the comparative effect of a water intake at a level of 1,000, 1,500, 2,000, 2,500, etc., c.c. for weeks and months in comparable cases. Until these observations have been made, much of the value of a prescribed water intake in influencing the course of nephritis must remain guesswork. Again, we are by no means sure that increased water intake is harmful in all types of nephritis. Just what has been said of water applies to food constituents. Salt intake, protein intake, the problem of an adequate diet in the newer sense, all need to be studied over prolonged periods. If we find that nitrogen elimination is decreased and there is nitrogen increase in the blood in the form of urea, uric acid, etc., we decrease protein intake, often with prompt improvement; but this condition of evident disturbance in nitrogen metabolism really comes late in nephritis. We need to know the optimum protein intake for the early stages, if we are to help matters. War conditions have shown that prolonged reduction of protein intake with a probable imbalance in amino-acid constituents is harmful. Excessive protein intake in the later stages is often observed to be harmful. Between these two extremes there are great gaps in our knowledge at present, and what the optimum intake over a long period of time should be with a mildly damaged kidney, we need to know.

So for salts, of which sodium chlorid almost alone has been studied and that only over relatively short periods of time. I want to impress on you that as to water, salt and protein intake, which we reduce with the idea of affording the kidney rest, and this seems to be sound in principle, we lack the knowledge as to what amount of each in combination is best for the developing nephritis in the sense of reducing renal work without causing other damage, and so affording a physiologic rest that will give the kidney the best opportunity to repair its damage. This information

apparently can be obtained by a thorough, careful study of a large group of patients, followed over a period of not less than five years, to whom we apply a considerable number of the methods of studying renal function at present available; and this surely should be done to give us a better basis for the dieting of patients with nephritis.

Apart from the various constituents of food, should the calory value of the intake in the nephritic be reduced to a level that will cause a loss of body weight, or should body weight remain in equilibrium? In diabetes, evidence seems to favor a lowered level of body weight. In the latter stages of both diabetes and nephritis there is a marked loss in body weight which cannot be made up by an increased calory intake. As to whether a lower level of body weight in the earlier stages of nephritis would be beneficial, we do not know. Careful observation here is almost lacking.

Muscle exertion increases substances to be eliminated by the kidney. Excessive muscular effort appears to lead to renal irritation. Too little exercise lowers the general efficiency of the body. We need to advise our patients with early nephritis in regard to exercise, yet we have few data on which to base our advice. Still, data would be obtainable if an adequate investigation of the effects of varying sorts and degrees of exercise repeated daily for a period of time should be undertaken.

2. *To Remove Edema.*—For this purpose we restrict salt and fluid intake and increase elimination. If we are to deal satisfactorily with edema we should know why the edema is produced. In some patients, apparently few in number, sodium chlorid retention in the body seems to be a very important causative factor in the edema. If salt retention is due to defective renal elimination, in such cases restriction in the salt intake frequently leads to disappearance of the edema. Whether or not this occurs seems to depend on whether, with a lowered intake, there is some excess excretion representing sodium chlorid taken from body stores. In ratio to this excess excretion, accumulated water leaves the body and edema decreases. With the reduction in salt intake, fluid intake too should be reduced to facilitate loss of fluid from the body. To reduce fluid and salt intake is evidently a rational procedure for patients with edema when we have evidence of faulty elimination of one or both. Unfortunately, however, in some cases water and salt excretion by the kidney is at such a low level that we are unable so to reduce intake as to bring about an elimination in excess of intake, and therefore our restrictive measures are ineffective. Fixation of salt and water by body tissues may play a part in causing edema. In many patients with edema we find a very poor salt elimination, and usually a decrease in fluid elimination. So far as can be detected, there is no considerable increase in salt and water in the vascular area as determined by analysis of the blood. In some of these patients a large part of the ingested salt, not excreted by the kidney, is found in such accumulations of fluid as ascites. We know that protoplasm contains both salt and water. Are these amounts, under certain conditions, increased in some way, more of these substances being incorporated or fixed in body cells? This is a phase of the subject, a biophysical one, about which we have little knowledge at present. There is much evidence that edema is by no means a simple question of salt and water retention

by reason of fault in the kidney. Certain edemas in which there is no evidence of renal lesion are proof of this. Anyhow, in actual practice, salt reduction and fluid restriction often fail to decrease the edema of chronic nephritis.

Another view has been expressed that in the edematous nephritic, blood proteins, mainly albumin, are decreased, and this decreases osmotic pressure to be exerted on the filtration membrane of the glomerulus and so increases water retention. To correct this, protein-rich feeding with high carbohydrate intake is advised. In my own trials such treatment has been ineffectual, and several observers fail to find evidence of decreased blood proteins. It would seem for both reasons that this is a factor in the edema in few cases. Usually protein-low feeding is advised on the basis of the principle of securing physiologic rest already referred to.

Another view of the causation of edema attributes it to swelling of colloids on account of increased acidity and variations in salt content. Alkalis are given on this basis; in my hands this treatment has been ineffectual and seems to be harmful.

Other theories as to the causation of edema do not lend themselves to therapeutic application. The entire question of the causation of edema needs thorough study; little is really known about it.

Failing to influence the edema by means planned to change conditions leading to its formation, we are forced to rely on increasing fluid elimination while restricting fluid intake. Naturally, the attempt is made to increase renal elimination by prodding the kidney to do more work; that is, diuretics are used. In edema of nephritis they are almost invariably ineffectual, and often are harmful. In circulatory edema they strikingly increase the excretion of urine, and in mixed circulatory and renal edema they may help. In my own experience I have never seen effective diuresis from a diuretic when the basis of the edema was a renal lesion. They may be tried cautiously, because one cannot be sure of the absence in a given case of a circulatory element in the edema responsive to diuretics, and perhaps there are cases with renal edema which may respond to a diuretic.

Fluid elimination can be brought about through skin and intestine, and sweating and catharsis will increase elimination of water. Unfortunately, they are processes that cannot be repeated very frequently (more than daily); they are debilitating at best, and progress by means of them is rather slow, even when it is obtained.

Mechanical removal of fluid can be carried out, and it always gives temporary relief; rarely is it of permanent help.

3. *To Prevent the Formation of Toxic Products and to Combat Their Effects.*—What causes uremia we do not know. It is a purely hypothetical toxic substance whose formation we seek to prevent or whose elimination we try to bring about. High protein feeding directly or indirectly frequently seems to precipitate toxic manifestations. Conversely low protein feeding should retard or prevent the formation of these toxic substances. We have evidence that it so works; therefore this type of nephritic (usually the nonedematous type), with reason, has a restricted protein diet prescribed. If these toxic substances are formed, we know of no way of neutralizing them; we can only seek to eliminate them. This we attempt by diuresis if possible, by catharsis and by diaphoresis; the last

two are the most effective means. With these we combine an increased fluid intake. Mechanical removal by bleeding is the promptest and most effectual means at hand. With bleeding, transfusion of normal blood is indicated in the anemic or when repeated bleeding is required.

In this review of the treatment of nephritis I have stressed the gaps in our knowledge with the idea of emphasizing the importance of further investigation of the problem of nephritis. Methods of treatment that we use are largely empiric; to recognize this fact is more conducive to investigation than if we assumed that treatment was on a rational basis. Notwithstanding the many deficiencies in our knowledge, we are able to do much to improve the condition of the nephritic, and probably we can retard the progress of the lesion which we cannot cure.

SUMMARY

Deficiencies in knowledge as to the etiology and pathology of chronic nephritis and associated vascular lesions handicap our treatment. Treatment is largely symptomatic and based on such knowledge as we possess of renal function. Preventive treatment is very unsatisfactory. In treating chronic nephritis we aim: (1) to stay the progress of the lesion; (2) to remove edema, and (3) to prevent the formation and combat the effects of toxic substances. To stay the progress, we seek to prevent infections, and by dietary restrictions to decrease renal work and so afford physiologic rest and opportunity for repair. The latter seems a rational procedure, but we need much knowledge for a basis of determining the optimum for a prolonged intake of water, salt and protein. To remove edema, we restrict salt and fluid intake and increase elimination; but we know very little as to the cause of edema, and hence are handicapped in treatment. Increased elimination by diuretics rarely succeeds when a renal lesion causes edema. Elimination by sweating and catharsis is slow, but may succeed. Mechanical removal is effectual, but temporary. To prevent toxic manifestations, we reduce protein intake; to combat them, we increase elimination by diuresis, diaphoresis, catharsis and bleeding. Bleeding is the promptest and most effectual method of elimination of toxic substances.

Peter Bent Brigham Hospital.

ABSTRACT OF DISCUSSION

DR. LEWELLYS F. BARKER, Baltimore: Dr. Christian distinguishes three main types: acute nephritis, the less acute or subchronic form with edema, and the chronic forms that go on for a long time without edema, though they sometimes develop a terminal edema from circulatory lesions. These groups correspond closely to the three generally described as acute diffuse nephritis, subacute or subchronic glomerular renal disease, and hypertension renal disease without edema, known as interstitial nephritis and as the arteriosclerotic kidney. I do not use the term interstitial nephritis unless confronted with an inflammatory condition. Ordinarily, I prefer the term nephropathy. The etiology of these diseases is not clear. Acute nephritis and acute inflammations are doubtless often toxic in origin and very often streptococci are responsible, especially for the subacute or subchronic glomerular tubular forms with dropsy and with edema. The cause of most chronic forms without edema is hypertension. We know less about these forms as far as etiology is concerned. Probably when we know the etiology of hypertension and of arteriosclerosis, we will be more familiar with the etiology of the chronic types. Obesity, hyperthyroidism and slight

infections occurring over and over again may be responsible. As to therapy: In focal diseases without any loss of renal tension, the therapy is simple, but in diffuse lesions with disturbance of the water output, with changes in or near the cardia, disturbance of the nitrogen output and the toxemia that seems to be associated with nitrogen retention, therapy is not so simple. Once nephritis in chronic form has occurred it is impossible to remove it. In the acute forms complete recovery sometimes occurs. Chronic renal disease with hypertension may go on for ten or twenty years and death finally occurs from uremia or myocardial insufficiency. As to the methods of protecting the kidney: The two principles followed are protection of the kidney and support of the heart and circulation. Protection of the kidney is most important in the first two groups and support of the heart is most important in the third group. The three dietetic regimens used are, first, water and milk, or a milk regimen; second, the chlorid-free regimen, and third, the nitrogen-free regimen. In any case of renal deficiency often only water, a wine-glassful every hour, will do good. The patient will suffer no harm by going without food for a few days. Often uremia and marked Cheyne-Stokes breathing will disappear under water regimen. Then give equal parts of water and milk, and finally, milk, but warning against a long continuance of such a regimen. To keep patients on nothing but milk for months is a mistake, since milk alone cannot support the patient properly. There is not enough iron in milk, and it is well to give iron in some form, such as Basham's mixture.

The indication for the chlorin-poor method is water retention with dropsy. In some cases this diet does get rid of the edema, but do not give a chlorin-free diet for too long a period. Give a chlorin-poor rather than a chlorin-free diet. Milk is not chlorin-free, but a pure vegetable diet is more nearly so. Chlorin-poor diet is so unpalatable that patients use pepper and mustard to flavor it. These substances are sometimes irritating to the kidney, and following large intakes of mustard many patients have developed gastric ulcer and hematemesis. The reduction of nitrogenous substances produces good results in the early stages but cannot be continued too long. It is important to keep the intestinal tract freely open by salines and to keep the skin moist. At the same time, avoid prolonged catharsis. Venesection is the quickest way of relieving uremia; often the withdrawal of from 300 to 600 c.c. of blood without any other measures will prove of value.

Some diuretics, such as theobromin sodium salicylate and theocin, may injure the kidney cells. I never give theobromin sodium salicylate for more than three days at a time or theocin for more than two days. The effects of these drugs are much more marked in the edemas due to myocardial insufficiency than to renal insufficiency. Squill also has some effect, but aside from theobromin sodium salicylate and theocin, diuretics do very little good. Support of the heart is important in the subacute cases with edema. Rest in bed with digitalis or strophanthus, reduction of the fluid intake to 500 c.c., five small meals, and laxatives, are the things that restore the heart muscle and circulation through the kidney. Prophylaxis is what we should preach. If we keep every patient with an acute tonsillitis in bed until the throat is well, if we take care of every acute infection by rest in bed, if we get rid of abscessed teeth and other focal infections before damage is done, if we keep patients from being 40 or 50 pounds overweight, if patients will have their family doctor examine them while they are well rather than wait until they are ill, we will accomplish more of what we desire.

DR. GEORGE DOCK, St. Louis: I do not think any advance has been made in our knowledge of kidney disease by trying to substitute the term nephropathy for nephritis. Some of the most typical cases of acute kidney disease are degenerative rather than inflammatory, hence the suffix "itis" cannot be limited to inflammatory processes. Nephritis can be translated "kidney trouble" rather than kidney inflammation. But kidney trouble is the same as nephropathy or nephrosis, and so nephritis is as accurate as any other term so far proposed. At the time the early classifications of kidney disease were

made, function was practically unknown. We have learned much about kidney function, but we have not translated kidney function into pathologic anatomy. There is much to learn. Dr. W. H. Olmsted has been working on a novel method, and with promising results. It consists, briefly, in letting the patient starve over night, examining the urine in concentrated form for the most important chemical constituents, then letting the patient drink large quantities of water (several liters), and then making a new series of chemical tests. I agree with Dr. Barker as to the preventive treatment of chronic nephritis. Osler called attention to the advantage of finding a small amount of albumin in the urine because the patient can be told that he has nephritis and his life be regulated so as not to be cut as short by the disease as it would be if he had no treatment. Often patients are given a bad prognosis because they have chronic Bright's disease and they live accordingly. Important points in practice are: Put the patient on a low calory diet early. A milk diet is fairly safe. Eggs are also good food in nephritic cases. Calcium, iron, bread and vegetables should be included in the diet. I prefer a salt free diet, because so many people do better with little salt. Some patients do better with red meat; some do better without meat, especially chronic cases of low grade without serious cardiac degeneration. I agree entirely with what has been said about diuretics. Exercise is important for these patients but it must be exercise suited to their condition. Chronic nephritis patients must be taught how to live.

DR. NELSON W. JANNEY, Santa Barbara, Calif.: There is still an overgreat tendency to overemphasize protein restriction in nephritics. One reason for this is the many laboratory investigations dealing with proteins, protein production, blood urea, etc., which has emphasized, perhaps too greatly, this phase of treatment. I have become accustomed to see nephritics in not a particularly favorable condition so far as the dietetic side of the treatment is concerned because of the low protein intake for a long period. Those patients are frequently rather weak and obese because the average man will make up promptly in fats and carbohydrates for what he is prevented from taking in the way of protein food. Obesity must be avoided in nephritis. The obese nephritic is usually weak and neurasthenic. Some of these patients are taking as low as 30 or 40 gm. of protein over long periods and really suffering protein starvation. Cutting down the fats and increasing the proteins help considerably. As regards the minimum protein requirement, Sherman allows 0.737 kg. of body weight. Many of these patients are given one fourth of that amount over long periods. When our knowledge of thyroid function increases, many patients with latent nephritis will be cured by treating the hypothyroidism. As in the treatment of diabetes we need a standardized dietary chart to record all data as to tests, etc. The correlation of treatment and the time period could then be worked out, in a much more satisfactory condition.

DR. EUGENE S. KILGORE, San Francisco: So long as we remain ignorant of the etiology of chronic nephritis it will be necessary to keep under suspicion a number of chemical substances used as medicines and food preservatives. Experience in investigating the effects on the kidneys of certain food preservatives has convinced me that such investigations as were possible heretofore are not decisive even if they fail to show kidney damage. It is possible that such substances may be injurious only when they have been administered over a very long time or only when in conjunction with an infectious or other agent. Still more suspicion must be attached to substances known to produce definite signs of kidney irritation. I refer particularly to the salicylates, which Hanzlik and his associates have shown to be followed quite regularly by the appearance of blood in the urine whenever the drug is given in full therapeutic doses. According to present evidence, salicylates seem to be more likely to injure the kidneys than to effect a cure. They are necessary for the relief of certain kinds of pain, but they should be used much less frequently than at present. For any other purpose than the relief of symptoms the legitimacy of their use is highly questionable.

DR. HENRY A. CHRISTIAN, Boston: I am heartily in accord with everything that has been said. I am a skeptic but not a pessimist. I have my doubts but I am not without hope. I expect to see great advances in this field. What we really need is not so many studies over a short period of time of such chronic conditions as nephritis, but studies over a long period of time. We cannot find out much about a disease that probably takes from five to twenty-five years from its inception to its end by studying it for a few days or a few weeks. We cannot find out very much about the methods of treatment unless we observe carefully the effect of remedial agents over a long period of time. What we need is combined study, because no one clinic is physically able to carry out such studies. An effort is being made through the National Research Council to carry out such a plan. That means finding the money because we have plenty of good people to carry out the work and to conduct such combined investigation over, let us say, a minimum period of five years. In regard to classification: study of a condition should be followed by simplicity rather than complexity. I sometimes take more liberties with classification than others, probably because I was trained as a pathologist who dealt with minute classifications. I think in dividing the disease clinically into acute nephritis, chronic nephritis with edema and chronic nephritis without edema, probably with the addition of a group of subacute nephritis, we have gone as far as we should in classification at present. A more satisfactory classification can come only from a more complete knowledge of nephritis clinically, etiologically and pathologically.

ARTERIAL HYPERTENSION ASSOCIATED WITH ENDOCRINE DYSCRASIA *

WILLIAM ENGELBACH, M.D.
ST. LOUIS

The purport of this paper is to offer additional evidence to the recent literature in which attempts have been made to associate a certain selected group of cases of arterial hypertension with disturbed internal secretions. In doing this the burden of proof is, first, to establish the existence of positive endocrine states in these cases; and, second, definitely to exclude the presence of a possible vasculorenal or other lesion as the cause of the arterial hypertension. With a few exceptions, the negative diagnosis of cardiovascular lesions in the cases here reported was based on the absence of present-day clinical manifestations and the course of the disease. The diagnoses of different endocrine dyscrasias were based on clinical evidence considered sufficient for the demonstration of positive endocrine disease, plus the exclusion of other possible diseases as a cause for the symptomatology. The personal observations here reported were deduced from an analysis of 500 uncomplicated endocrine diseases, in which accurate blood pressure records and other determinations worthy of report had been made. Of these 500 patients, forty-six had a systolic pressure of 160 or above. This surprisingly high number, almost 10 per cent., was considered of sufficient clinical importance to be worthy of attention, and serves as the pretext for this paper. In a considerable number of these cases, the abnormal blood pressure had been diagnosed as being due to "neurosis," or to lesions of the renal or vascular system. Contrary to the unfavorable prognosis based on renal or vascular disease, many of these patients had lived a considerable number of years, completely disregarding their high

blood pressure or other serious lesions held responsible for this sign. The treatment which had been prescribed, definitely indicated, no doubt, by the foregoing diagnosis, if in any way effective, had only served to add materially to the affliction of these patients.

In order to avoid early misconception regarding the possible relationship of endocrine states to arterial hypertension, it should be stated that there is no intention to disconnect arterial hypertension from the already well-established groups of arteriorenal lesions. The scope of this paper covers an entirely different division of cases, perhaps a small percentage of the entire number of arterial hypertensions, the clinical studies of which suggest an entirely different cause for the high blood pressure. Granted that this premise is correct, then the prognosis and treatment in these cases must, of necessity, be radically different from those that are accepted in arterial hypertension.

RELATIONSHIP OF ARTERIAL HYPOTENSION TO ENDOCRINE DISEASE

Since Addison first described epinephrin insufficiency in 1855, there has been a tendency to relate different blood pressure states to abnormal activities of the endocrine glands. The gradual decrease in blood pressure in complete insufficiency of the suprarenal glands not only attracted the attention of physiologists and clinicians (Vaquez and Aubertin,¹ Schur and Wiesel,² Ehrmann, Schlayer,³ Fränkel,⁴ Aschoff and Cohn,⁵ Oberndorfer,⁶ Stewart,⁷ Ingier and Schmorl,⁸ Janeway and Park⁹) to this relationship, but the trend of experimentation has been along the line of attempting to connect arterial diseases and those substances of the internal secretions which are known to influence markedly the unstriated muscle contractions producing constriction of these vessels. Allbutt¹⁰ has described and proved the involutionary or decreascent type of arteriosclerosis in which the arterial tension gradually decreases, adding to the clinical groups of arteriosclerosis an entirely different syndrome from that in which hypertension is associated with sclerotic changes of the vascular system.

For many years the secretion from the thyroid gland has been thought to be an antagonistic hormone to epinephrin in its effect on vasoconstriction. For instance, it is thought that thyroid secretion neutralizes the effect of epinephrin on the general muscular tonus, and particularly on the vasomotor constriction of the vascular system. Mikulicz, in his description of senility, gave, as a probable cause, the early atrophy and decreased secretion of the thyroid gland and consequent withdrawal of the vasodilator neutralizing effect of this secretion on the vascular system, allowing the epinephrin secretion to exert its pressor effect uninfluenced. Many other authorities (Weber, Lorand, Ewald, Rolleston and Williams¹¹) suggested insufficiency of the thyroid secretion as a possible cause for

the so-called senile, involutionary or decrescent type (Allbutt) of arteriosclerosis associated with hypotension. On the other hand, Victor Horsley,¹² Rolleston,¹³ and others have denied such relationship. Allbutt, in his exhaustive specialized observation on this particular type of arteriosclerosis, reports negative effects on the hypotension from thyroid therapy.

It has been generally recognized, clinically, that arteriosclerosis is a rather common accompaniment of cretinism, as well as of gout and other so-called metabolic diseases. On the other hand, the changes of the blood pressure in different cases of myxedema cannot be attributed solely to the lack of thyroid substance. If this were true, the pressure would rise in all cases, whereas it is only in a comparatively small percentage of cases that abnormal arterial tension, either increased or decreased, has been noted. Spiethoff,¹⁴ Maire,¹⁵ and Treves¹⁶ found a variable blood pressure compared to the thyroid activity and other symptomatology of hyperthyroidism. Changes in the blood pressure during the climacteric have been assigned by Wilson¹⁷ to the fact that the internal secretion from the ovary has a marked vasodilator effect on the arteries, and that consequently its absence during the menopause is a factor in the rise of the blood pressure in this peculiar group of cases. Nevertheless, the hypertension in these cases must be due to causes other than the disturbed secretion of the ovaries, otherwise, it would occur in a larger percentage of cases. The chromaffin secretion is supposed to influence the sympathetic, and not the autonomic nervous system. Other explanations (Gaskell, Cushny, Dixon and Harvey¹⁸) for the peculiar localized vasoconstriction effect on the vascular system have been attributed to the different amounts of epinephrin contained in the blood in different arteries of the body. Stewart⁷ has proved that none of the theories mentioned above has been substantiated convincingly enough to give them consideration.

THE PATHOGENESIS OF ARTERIAL HYPERTENSION

Despite the prodigious amount of work since Traube¹⁹ expounded his mechanical theory of renal vasoconstriction as the cause of increased blood pressure in 1856, the genesis of arterial hypertension has remained unsolved. It would not be pertinent at this time to attempt to classify the various theories assigned to this interesting sign. Suffice it to say that a great many theories have been advanced which propound other than actual organic or structural changes in the arteriorenal system as the causative factor for the high blood pressure. Those well-known structural lesions of the cardiovascular system, so commonly associated with high blood pressure will be omitted from this discussion; they will be placed in a different group from those which I shall describe. The type of arterial hypertension under consideration is supposed to be entirely dissociated from vasculorenal lesions, or if such lesions, as late changes, are present, the hypertension, it is assumed, antedates them by many years. It is presumable that when such high blood pressure exists for a period of years, arterio-

sclerosis results as an effect (but is not the cause), and that terminal changes such as cerebral hemorrhage and cardiac insufficiency (but never uremia) may be the end-result in these cases. Considerable controversy obtained in the early literature about just such cases of arterial hypertension, and these terms were assigned by various authors to these arterial hypertensions: (1) "prealbuminuric stage of Bright's disease" (Mahomed,²⁰ 1879); (2) "latent sclerosis" (von Basch); (3) "presclerosis" (Huchard, 1893); (4) "essential hypertension" (Krehl,²¹ and Mosenthal and Hamman²²); (5) "hyperpiesia" (Allbutt, 1894); (6) "angiosclerosis" (Thoma); (7) "pure hypertension" (Josué and Block²³); (8) "neurotic hypertension" (Bradford, 1898); (9) "primary cardiovascular hypertension" (Janeway,²⁴ 1906); (10) "benign hypertension" (Vohlhardt and Fahr), and (11) "functional hypertension" (Martinet,²⁵ 1912). Just what relation the diseases of the ductless glands bear to the types of hypertension just enumerated cannot be determined. It is probable, however, that a better knowledge of the diagnosis of internal secretion may reflect considerable light on the etiology of these so-called nonvasculorenal types. Should this occur, it may help to explain why a great many of the exogenous causes, such as mental strain, heredity, intoxications and infections, which have such a marked effect on the secretions of the ductless glands, have been given so constantly as etiological factors for arterial hypertension.

It may also help to explain why obesity and other metabolic states are so frequently associated with arterial hypertension. While it is true that as yet no convincing proof has been offered, either by histopathology or physiologic chemistry, for the direct association of arterial hypertonia with endocrine dyscrasias, there is, nevertheless, increasing clinical evidence that arterial hypertension does exist in positive endocrine cases in which there is no definite manifestation of either vascular or renal disease.

INCIDENCE OF NONVASCULORENAL ARTERIAL HYPERTENSION

Janeway, after setting aside all doubtful cases, found among 130 patients with blood pressure of over 200 that no renal disorder could be detected in seventeen cases, or 13 per cent. He called these cases "primary cardiovascular hypertensions." In 100 cases of arterial hypertension studied very exhaustively by Rappleye,²⁶ in forty-five cases, or almost 50 per cent., there was practically negative urine, blood urea, blood nitrogen, and phenolsulphonophthalein output. In 100 cases reported by Schneider,²⁷ seventeen were classified as "benign" or "essential hypertension," on this basis: (1) normal vessels; (2) retention of concentrating power of the urine (Mosenthal's test); (3) normal urine, with the exception of an occasional hyaline cast and a trace of albumin; (4) phenolsulphonophthalein output normal or slightly below normal, and (5) normal blood urea and creatinin. He states, however, that, if these cases were observed long enough, from 10 to 20 per cent. would later be classed with the

malignant or nephritic groups. Of these 100 cases, 5 per cent. were grouped with the type due to endocrine dyscrasias; 3 per cent. to exophthalmic goiter; and 2 per cent. to the climacterium. An analysis of this report, based on 500 endocrine cases, demonstrates that forty-six, or nearly 10 per cent., were associated with high blood pressure. Furthermore, in a general consideration of all the cases of arterial hypertension personally observed, comparatively few have been found independent of the vasculorenal lesions which could not be classified in this group.

RECENT LITERATURE ASSOCIATING ARTERIAL HYPERTENSION WITH ENDOCRINE DYSCRASIA

During the last year there have been three papers (Riesman,²⁸ Hopkins,²⁹ and Gutmann³⁰) referable to increased hypertension associated with the menopause. Spiethoff, from an analysis of twenty cases of exophthalmic goiter, found a variable blood pressure dissociated from the general symptomatology. With these exceptions, there has been comparatively little literature extant referable to any number of endocrine states or cases associated with high blood pressure. Isolated cases of endocrine diseases have been reported, in which high blood pressure has been noted. Gibson³¹ suggested the idea of an association of arteriosclerosis with pituitary disorder, and reported a number of cases in which there was arterial hypertension. Riesman²⁸ noted, besides the relation of arterial hypertension to the climacteric, its presence in both pituitarism and thyroidism. Hopkins,²⁹ in two exhaustive papers, has fully described this relationship of arterial hypertonia to the menopause. Plummer has noted its incidence in thyroidism.

In the forty-six cases here reported, it will be noted that high blood pressure was found associated with disturbed activity of various ductless glands, occurring in both sexes and in ages other than that of the menopause. The largest percentage of cases was grouped with those in which occurred polyglandular insufficiency, involving the thyroid and the pituitary gland. It was found associated, however, in cases in which apparently but one endocrine gland was involved.

ABSTRACTS OF ILLUSTRATIVE CASES

CASE 1 (General 1259).—Diagnosis: Polyglandular insufficiency (*hypopituitarism and hypothyroidism*). Blood pressure (before treatment), 200 mm.; (after treatment), 160/95 mm.

History.—Mrs. E. S., aged 38, referred by Dr. F. H. Lamb, Davenport, Iowa, complained of marked fatigability; dyspnea on effort; nervousness, emotionalism, and headaches, of six years' duration. The onset of these symptoms had been gradual, with attacks of weakness, increasing fatigability, nervousness, emotionalism and headaches. One year after the onset, she suffered from attacks of very marked abdominal distention or bloating, associated with belching and constipation. During the entire course of the symptoms she had gained 85 pounds in weight, 25 pounds within the last eight months. There had also been irregular periods of polyphagia, polyuria and polydipsia. The hands and feet had been swollen and stiff intermittently during the last few years. She had suffered from somnolence, a marked complaint during the day, and insomnia at night. She had had measles and mumps during childhood, and bronchitis at the age of 16. Other findings were negative, except the menstrual. She had matured at 11½ years, since when the menses had been

irregular, of three days' duration and the flow had been scanty. During the last two years, the flow had increased in amount and had been associated with slight dysmenorrhea. The patient's mother had died at the age of 76. She had been very obese, drowsy and somnolent for years. The cause of her death was unknown. One sister was very obese; four others were living and well. One brother was very obese, and had been relieved by thyroid treatment. One brother had very high blood pressure.

Examination.—The measurements were: from the symphysis to the soles of the feet, 32 inches (81 cm.); from the symphysis to the vertex, 34 inches (86 cm.), and the span was 70 inches (178 cm.). She was a large woman, weighing 207¼ pounds, with a tendency to the girdle type of obesity. There was considerable fulness through the thighs, and padding about the hypogastrium and over the mons. There was some enlargement of the legs and arms, with evidence of subdermal thickening. The skin was dry, and there was a fine desquamation. There was a slight growth of hair on the legs, but no abnormal distribution about other portions of the body. The hands were of the thyropituitary type: the fingers were tapering, the lunular markings were faintly visible, and there was definite puffing of the backs of the fingers and hands. The feet were of the same character. The color of the body was good and of the face, very good. The systolic blood pressure before treatment was 200 mm. of mercury; and after treatment, 160/95 mm. Regional examination was negative, except for evidence of an endocrine heart. A systolic murmur was heard over the pulmonic area, which disappeared on inspiration. The aortic second sound was slightly accentuated. Palpable arteries were not sclerosed. Single catheterized and twenty-four hour specimens of urine were negative. The phenolsulphonephthalein test gave a total of 85 per cent. Blood analysis revealed: hemoglobin, 110 per cent.; white blood cells, 12,600; red blood cells, 5,670,000. A smear and Wassermann reaction were negative. Nonprotein nitrogen was 25 mg. Sugar tolerance was normal. Blood sugar (after fifteen hours' fasting) was 0.130 (normal, from 0.10 to 0.120); one hour after 162 gm. glucose, 0.219 (normal, 0.180); two hours after 162 gm. glucose, 0.099 (normal, from 0.10 to 0.150). Basal metabolism (Benedict's) had decreased 10 per cent.

CASE 2 (General 1150).—Diagnosis: Polyglandular insufficiency, hypopituitarism and hypothyroidism (*pituitary hibernation*). (*Achylia and spastic colon*.) Blood pressure, 198/140 mm.

History.—Mr. C. W. M., aged 58, complained of marked somnolence (he was unable to remain awake unless actively engaged in some physical procedure); nocturnal insomnia and attacks of dyspnea, attacks of gastric disturbances, distention, fulness and pressure in the epigastrium; gradual gain of weight to 255 pounds, and high blood pressure, from 205 to 220 mm., of five years' duration. Somnolence had been gradual during the last few years, the patient being unable to keep awake while reading or talking. The onset of obesity was gradual; a few years before there had been a gain of 10 pounds within five weeks. High blood pressure, recording over 200 mm., had been first noted five years before, at the age of 53. He had suffered from nocturnal insomnia and dyspnea during the last year, and had had to assume the semireclining position for sleep. Dyspnea was present usually in the early morning hours. He had suffered an attack of renal colic several years before. He had had influenza one year before, and an operation on the nose, under a local anesthetic. The tonsils had been removed thirty years before. He had suffered from migraine during the ages of 16 and 17, but not since that age. He was a mild user of tobacco, and an inordinate eater. One sister had nephritis and his mother had migraine.

Examination.—The patient weighed 255 pounds. The lower measurement was 36 inches (91.5 cm.) and the upper measurement, 37 inches (94 cm.); the span was 76 inches (193 cm.). There was an osseous development of probable pre-adolescent anterior lobe hyperpituitarism. There was considerable obesity, but no extreme broadening through the hips. The abdomen was prominent; there was some bulging in the flanks, and a very slight padding about the mons.

31. Gibson: Address on Medicine, Liverpool, 1912.

There was a slight abnormal distribution of hair on the upper abdomen; none on the chest, and a slight growth on the legs and arms. There was no edema, very slight pitting on pressure and no marked subdermal thickening. There were a few indifferent scars and pigmentations about the shins. The hands were of the pituitary type: the palms were broad, the fingers fairly long and tapering, and the lunular markings faintly visible. The feet were of the same general character. The skin was somewhat dry, showing very fine desquamation. The hands and feet were warm. The color of the body was good, the face was florid, and there was a slight general sallowness. There was no muscular atrophy, no abnormality of gait or station, and no cyanosis or dyspnea. The pulse was moderately slow, regular, with a quick rise and fall, equal and symmetrical. There was no pistol-shot sign in the forearm, nor Quincke sign visible in the finger nails. The blood pressure was 198/140 mm. There was a systolic murmur in the pulmonic area, which disappeared on deep inspiration. The second aortic sound was accentuated. The palpable arteries were easily compressed and not thickened or tortuous. The roentgen ray revealed a normal sella turcica (12 by 13 mm.). Stereoscopic examination of the chest revealed fullness over the right auricle and a normal aortic shadow. There were suggestive shadows of calculi in the left kidney. Fluoroscopic examination of the chest revealed aorta, heart, diaphragm, stomach and colon normal. Blood examination revealed: hemoglobin, 76 per cent.; red blood cells, 4,460,000; white blood cells, 8,400; differential count and stained smear, normal; Wassermann reaction, negative. Examination of stomach contents disclosed free hydrochloric acid, negative; otherwise normal. There was a trace of albumin in the urine. The phenol-sulphonaphthalein test gave a total of 38 per cent. Blood sugar (after fifteen hours' fast) was 0.120; one hour after 194 gm. glucose, 0.246; two hours after 194 gm. glucose, 0.180. The basal metabolism decreased 25 per cent. (Benedict's). Electrocardiographic examination revealed an absence of preponderance of the left ventricle.

Treatment and Results.—The patient was placed on thyro-pituitary substitution treatment (and hydrochloric acid and essence of pepsin for the achylia). The result of the therapy during two months' observation was complete relief of the gastric disturbances, somnolence, nocturnal insomnia and dyspnea, and reduction of the blood pressure to 154 mm. and of the weight to 220 pounds.

CASE 3. (General 1260).—Diagnosis: Hyperpituitarism and hyperthyroidism. Blood pressure, 220/135 mm.

History.—Mr. H. S., aged 45, referred by Dr. J. E. Jost, Jefferson City, Mo., complained of attacks of headache, vertigo, weakness, nervousness, insomnia and loss of memory; high blood pressure, above 200 mm.; loss of weight, amounting to 40 pounds during eighteen months, and marked attacks of dyspnea. The high blood pressure had been present for six years. The onset was gradual, with a mild sensation of fullness in the head, and vertigo, eight years before. Two years following this, high blood pressure was noted at examination, the systolic pressure being 190, and failing to react to dietetic, medicinal, electric or hydrotherapeutic treatment. Following the onset of the disturbance, there were terrific attacks of headache, with extreme vertigo, throbbing sensations and memory defect. There was loss of hearing in the left ear during the third year of the disease. Attacks of abdominal distention had been present during the last eighteen months, for which the patient frequently took repeated enemas, without relief. Following the onset of this disturbance, he began to lose weight, which loss had totaled 40 pounds during the last year and a half. He had suffered from no infectious diseases, no operations and no injuries. He did not use tea or coffee, he chewed tobacco, seldom smoked, used alcohol moderately, and had discontinued its use for the last seven years. The family history was negative.

Examination.—The measurements were: from the symphysis to the soles of the feet, 35¼ inches (89.5 cm.); from the symphysis to the vertex, 32½ inches (82.5 cm.); the span was 72 inches (183 cm.). The general development was good; there was some loss of weight but no marked evidence of

emaciation. There was an osteochondroma on the inner aspect of the left leg, just below the knee. There was a marked growth of hair on the legs, with abnormal distribution on the upper abdomen, chest and forearms. There was a slight pallor of the body, but the color of the face was very good. The hands were long; the fingers were not tapering; the lunular markings were visible, and there was slight cyanosis of the nails. There was no edema or dyspnea, and no abnormality of gait or station. The thyroid was not enlarged. The systolic murmur in the anterior axillary line was not modified by respiration. There was marked accentuation of the second tone at the base. The systolic murmur heard at the base was transmitted upward, along the right side to the carotid, on the left side as high as the clavicle, and disappeared entirely on deep inspiration. There was marked accentuation of both second tones, and no tortuosity, motile pulsation or sclerosis of the superficial vessels. The blood pressure was 220/135 mm. There was a trace of albumin in the urine. The phenol-sulphonaphthalein test gave a total of 52 per cent. Blood examination revealed: hemoglobin, 110 per cent.; red blood cells, 5,910,000; white blood cells, 6,800. A stained smear and differential count were normal; the Wassermann reaction was negative. Blood sugar (after fifteen hours' fasting) was 0.116; one hour after 115.3 gm. glucose, 0.148; two hours after 115.3 gm. glucose, 0.132. The non-protein nitrogen content was 25 mg. Fluoroscopic examination revealed normal head, neck, chest, heart, mediastinum and diaphragm. Electrocardiographic examination disclosed absence of left ventricular preponderance. Basal metabolism had increased 4 per cent.

CASE 4 (General 1197).—Diagnosis: Menopause (hypothyroidism and hypo-ovarianism). Blood pressure, 220/130 mm.

History.—Mrs. S. B. C., aged 53, complained of a throbbing sensation in the head, tinnitus; dyspnea on exertion; nervousness and insomnia; abdominal distention and constipation; of four years' duration, from the time of the menopause (age 49); blood pressure, 210 mm. The onset had been gradual, with nervousness, insomnia, a throbbing sensation in the head, and headaches. Soon afterward an abdominal syndrome began, consisting of distention, constipation, a sensation of gurgling, and diffuse tenderness. There were no localized or focal symptoms or complexes resembling appendicitis or gallbladder or renal disease. During the course of the patient's disease, she was in bed three times with attacks of so-called sciatica, which were limited to the hip, never occurring along the course of the sciatic, and never being associated with temperature or localized tenderness. Arterial hypertension was first noted two years before, since which time it has fluctuated during twenty-four hour intervals, from 210 to 150 mm. She had had measles, mumps, whooping cough and chickenpox. She had undergone two operations: a perineorrhaphy and amputation of the breast for benign tumor. The menstrual history was normal, with the exception of a scanty flow and a menopause which occurred at the late age of 49. The family history was negative.

Examination.—The measurements were: from the symphysis to the soles of the feet, 34 inches (86.25 cm.); from the symphysis to the vertex, 32½ inches (82.5 cm.); the span was 67½ inches (171.5 cm.). The patient was a large woman, but well built and without abnormal obesity. There was slight fullness through the hips (not abnormal); no fullness over the hypogastrium or mons; very slight growth of hair on the lower extremities, and no abnormal distribution on the upper extremities. There was an erythematous blush on the base of the neck and upper chest. The hands were long and fairly slender; the fingers inclined to taper, and the lunular markings were visible. There was no edema, cyanosis or dyspnea, and no abnormality of gait or station. The color of the body and face was good. The thyroid was normal. There was a diffuse impulse over the precordia, accentuated by nervousness. The apex beat was heard in fourth interspace, at about the midclavicular line, forceful but not heaving. There was no palpable thrill or diastolic shock. Borders, apex beat, midsternal line. The first tone at the apex was loud and booming, followed by a short

systolic murmur, which disappeared on inspiration (cardio-respiratory). The same murmur was heard in the pulmonic area, and a similar murmur in the aortic region, which disappeared on inspiration. The aortic second sound was accentuated and sharpened. The pulse was moderately rapid, of fair volume and tension, regular, equal and symmetrical. The peripheral vessels were free from mobile pulsations, not tortuous, nodular or sclerosed. The blood pressure was 220/130 mm. Single and twenty-four hour specimens of urine were normal. The phenolsulphonephthalein test gave a total of 60 per cent. Blood examination revealed: hemoglobin, 104 per cent.; white blood cells, 7,200; red blood cells, 5,140,000. A stained smear was normal; the Wassermann reaction was negative. Nonprotein nitrogen was 23 mg. Blood sugar (after fifteen hours' fasting) was 0.090; one hour after 111 gm. glucose, 0.159, and two hours after 111 gm. glucose, 0.111. Basal metabolism decreased 18 per cent. Fluoroscopic examination of the head, neck, lungs, thoracic vessels, mediastinum and diaphragm was normal; there was very slight left ventricular hypertrophy. Electrocardiographic examination revealed a slight left ventricular preponderance.

Treatment and Results.—Under one week's treatment, consisting of thyroid and corpus luteum substitution, the blood pressure dropped to 144, and remained below 150 for three weeks.

CLASSIFICATION OF CASES

1. Pituitary gland	5
(a) Hypopituitarism	4
Simple hypopituitarism	1
Pituitary headache	1
Eunuchoid gigantism	2
(b) Hyperpituitarism	1
Pituitary glycosuria	1
2. Thyroid gland	12
(a) Hypothyroidism	8
(b) Hyperthyroidism	4
3. Ovaries	15
(a) Menopause	11
Associated with hypothyroidism	4
Associated with hyperthyroidism	3
Associated with hypopituitarism	2
Associated with eunuchoidism	1
Associated with migraine (pituitary?)	1
(b) Gonad	4
Eunuchoidism	1
Early castrate	1
Late castrate (with hypothyroidism)	2
4. Polyglandular	14
(a) Pituitary and thyroid	12
Simple pituitary and thyroid insufficiency	9
Associated with pituitary headache	1
Associated with hibernation	1
Hypersecretion of pituitary and thyroid	1
(b) Thyroid and gonad insufficiency	1
(c) Pituitary, thyroid and gonad insufficiency	1
Total	46

ANALYSIS OF PERSONAL OBSERVATIONS

In an analysis of more than 500 endocrine cases observed during the last four years, it was found that forty-six, or about 10 per cent., had a blood pressure above 160. Those cases in which a diagnosis of nephritis or arteriosclerosis was suspected were excluded. Of the forty-six, the highest percentage of arterial hypertension was found among the pluriglandular dyscrasias. Fourteen of the forty-six, or 30 per cent., were classified as having more than one gland involved, with none so sufficiently dominating the picture or initiating its course that it might be considered the primary secretory disturbance, with the other glands classed as secondary. Combinations of the pituitary and thyroid hyposecretions were present in twelve cases, or about 26 per cent., of the hypertensive cases. The next highest percentage, eleven cases, or one fourth of the entire number, occurred at the menopause. In cases in which there were glandular disturbances apparent in this group, they were merely considered as a part of the climacteric. For instance, in four there was evidence of hypothyroidism; in three, hyperthyroidism, and in two, hypopituitarism. Of the

primary gonad insufficiencies, there were four cases, or 9 per cent.; one in a eunuchoid person, two in a late, and one in an early castrate. The next in frequency was the thyroid group, with eight cases, or 17 per cent., classified as pure hypothyroids, and four, or 8 per cent., as hyperthyroids. The pituitary group ranged lowest in number, five cases, or 11 per cent., being classified as simple dyscrasias of this gland. Of this number, four were hypopituitarism and one hyperpituitarism. One of these was a case of pituitary hibernation, one a case of pituitary headache (both reacted to substitution pituitary treatment), one a hypophysial glycosuria, and two eunuchoid giants.

DIAGNOSIS

The diagnosis of this type of arterial hypertension is necessarily difficult and perhaps many times questionable. The important diagnostic objectives are the exclusion of the following organic lesions: (1) renal disease; (2) cardiovascular disease; (3) subacute or chronic infections (focal and general) and intoxications (syphilis, lead poisoning, gout, etc.); (4) other conditions producing arterial hypertension (increased viscosity of the blood in plethoric individuals, obesity, diabetes, migraine, organic nervous diseases, 'pregnancy, eclampsia, premenstrual arterial hypertension, and intermittent or paroxysmal hypertension).

1. The first essential is to exclude, if possible, all varieties of renal disease. Dependence has been placed on complete and prolonged observation of the case, including repeated urine analyses, concentration power of the kidney (Mosenthal renal test), the phenolsulphonephthalein functional test, blood retention products (total nonprotein nitrogen, urea, creatinin and uric acid), retinal changes, and cardiovascular signs ordinarily associated with renal disease, such as cor renale, left ventricular preponderance (electrocardiogram), and accentuation of the second aortic tone. The variability of the blood pressure has been an important differential sign. Marked vacillation of from 40 to 60 mm. of pressure in twelve hours, or a rapid reduction of the pressure of more than 60 mm. by treatment, has been considered not due to renal disease. For instance, in Case 4, reported in this article, the systolic pressure, according to the history, had varied from 210 to 150, and quickly fell from 220 to 134 after three days of a treatment that allowed the patient a regimen of moderate exercise, a liberal diet, and freedom from eliminants and vasodilators. On such non-nephritic treatment, the pressure remained below 150 for the following two weeks.

2. The exclusion of arteriosclerosis is another very difficult problem. It is well known that there is frequent sclerosis of the visceral arteries, with absence of all signs of sclerosis of the superficial or palpable vessels. A history of a previous disease that might have produced either arteriosclerotic degeneration or renal lesion, or a thickening, nodulation, tortuosity or pulsating mobility of the superficial vessels is, of course, significant. Changes in the conjunctival and retinal vessels, or changes in the arch of the aorta or the left ventricle of the heart (demonstrated by roentgenologic examination) must also be sought. The clinical symptoms that are frequently associated with visceral sclerosis, sclerotic dementia and angina pectoris, abdominis and cruris are valuable diagnostic aids.

3. Besides the foregoing negative evidence for vasculorenal disease, there should also be negative evi-

dence for focal or general infections, which frequently have a very decided effect on arterial tension. This also pertains to subacute or chronic intoxications and other metabolic diseases, such as plumbism and gout.

4. The fourth group of conditions which must be borne in mind borders very closely on the type of arterial hypertension that has been under discussion as being associated with endocrinous states; possibly some of these should really belong to the group described. Bac,³² in a recent publication, has renewed the interest in the viscosity of the blood as a possible cause for arterial hypertension in plethoric or obese persons. The intermittent or paroxysmal hypertensions present in migraine, pregnancy, eclampsia and the premenstrual state, or in other so-called functional, neurotic or emotional arterial hypertensions, would probably either fall within this class of arterial hypertensions, or be disqualified entirely, because not persisting for sufficient time to be classified as a definite syndrome. Their differentiation depends on repeated blood pressure observations during the same day, or for a number of consecutive days. In fact, a single blood pressure reading is unreliable, and needs many confirmations. In the great majority of the cases that I have observed, the initial blood pressure reading was usually entirely disregarded, on account of being from 20 to 40 mm. higher than the average procured by making daily examinations. At the same time, the daily variation and the susceptibility of the patient to temporary impressions must, of course, be given consideration in making the final average estimation of the blood pressure.

It must be acknowledged that even after the most searching observations, all clinical evidence sufficient to differentiate and exclude renal and vascular lesions may be lacking, and yet a positive renal or arterial lesion be present. This fact must be borne in mind in each individual case; otherwise, the diagnosis in these cases is subject to a certain percentage of error.

Besides the foregoing negative evidence, there must be present in each of these cases a sufficient history and a definite syndrome of demonstrable endocrine disturbance to account completely for the symptomatology.

PROGNOSIS

The prognosis in these cases is very much more favorable than in those in which there is high arterial tension due to definite vasculorenal lesions. Their course is much longer and less beset with disturbing symptoms than other types of arterial hypertonia. It is true that many of them develop arterial disease, sooner or later; possibly others develop renal disease. The termination of these cases is rarely that accompanying any of the nephropathic diseases, such as uremia. If the arterial tension is not reduced or reducible, many cases terminate from cerebral hemorrhage or cardiac incompetence. For this reason, the term "benign or functional hypertension" is a misnomer, since the high blood pressure is certainly one in which the indications for treatment are just as urgent as in those due to other causes.

TREATMENT

The treatment depends entirely on the treatment of internal secretory dyscrasia, with which this abnormal hypertonus is associated. The general indications for treatment are merely those of correcting, if possible,

the disturbed internal secretory balance. If this can be accomplished, in the majority of the cases the blood pressure will be very much reduced, and frequently return to and remain within normal limits. It can readily be understood that the treatment for these cases is entirely different from that directed toward nephritic or arteriosclerotic hypertension.

The low protein and salt-free diet, as ordinarily recommended for these conditions, has no basis in the majority of cases. Increased elimination, ordinarily applied to the nephritic cases, is also frequently contraindicated. It has been noted, in some of these cases, that the drugs which appear to be absolutely contraindicated in other types of arterial hypertension, on account of their vasoconstriction effects, are really applicable and effective agents. For instance, pituitary extract (hypophysial posterior lobe extract) has been demonstrated actually to reduce the blood pressure in pituitary hibernation, probably on account of its effect on the carbohydrate or fat metabolism, which is the basic fault or cause of the arterial hypertension in these cases. Epinephrin, on account of its hormone effect on the gonads, might also be indicated in the menopause or gonad types. In the hypersecretory cases, such as hyperthyroidism and hyperpituitarism, surgery might even play a rôle in an attempt to relieve the high blood pressure. This is an instance in which arterial hypertension itself would not be a contraindication to a surgical operation, provided the diagnosis is sufficiently clear to prove that the increased secretion from these glands is its sole cause.

923-934 University Club Building.

ABSTRACT OF DISCUSSION

DR. FRANCIS M. POTTENGER, Monrovia, Calif.: We have studied the cause of disease, and the results of disease, but we have neglected to study how the cause operates to produce the effect. Nerve control and internal secretions are two factors through which stimuli operate to produce results. A symptom is a resultant of all stimuli. Consequently, it is difficult to say that any one produces this result. We must learn how to analyze conditions and then determine the results. We must bear in mind also the psychical condition. Nearly all neurotics are merely psychics. Stimuli are discharged either through the nervous system or through the endocrine system and upset balance. The result may be a hyperarterial tension or a hypoarterial tension. These are the conditions that must be studied.

DR. GUSTAVE ROUSSY, Paris, France: (Dr. W. S. Thayer, Baltimore, translated the substance of Dr. Roussy's remarks.) Dr. Roussy refers to the observations made some years ago by Josué, who provoked a disease of the vessels, an arteriosclerosis, in rabbits by treatment with the suprarenals. The frequency of suprarenal changes in hypertension in arteriosclerosis was also studied by Mendel and others, who pointed out particularly the changes in the cortical part of the suprarenals. Vaquez demanded further whether this were, perhaps, after all not the primary element in many of these instances of hypertension, clinical hypertension, and anatomic arteriosclerosis.

Dr. Roussy studied with Dr. Clunet, about 1,000 cases, carefully, anatomically. In 200 cases, a systemic examination was made of the glands of internal secretion, and in many instances definite changes were made out, very commonly in the suprarenals and particularly in the cortical substance; sometimes there was a hyperplasia of the pituitary body, especially of the chromophil cells or eosinophils, while the chromophil cells were increased. Also sometimes changes in the thyroid were present; hyperplastic changes were found in the parathyroids. In some instances well marked arteriosclerosis and hyperplasia of the suprarenals were also noted. Dr. Roussy pointed out that there are other

instances of arteriosclerosis in which changes in the glands of internal secretion are not to be made out. One should study and consider not only the anatomic conditions, but the interpretation of those conditions. In some cases of arteriosclerosis the suprarenals are affected; in others, they are not. The coincidence of the arteriosclerosis and the lesions of glands of internal secretion may be interpreted in the sense that the arteriosclerosis is purely secondary to the hyperplastic changes in the glands of internal secretion. It may be, on the other hand, that the converse is true, that the changes in the glands of internal secretion may be secondary to the changes in the vessels; or lastly, they both may be the result of some other condition of which we are as yet not cognizant. At this moment the explanations are hypothetical. It is a very important matter for further study.

DR. C. J. FISHMAN, Oklahoma City: Clinically, we occasionally see a type of case in which we may say that the endocrine system is affected, namely, in cases of high blood pressure, with a mild degree of glycosuria. We must remember that glycosuria may be produced by injections of suprarenal, and that this substance also produces an increased blood pressure. That is one basis for conclusion. Another basis is that clinically these cases of high blood pressure, with a mild degree of glycosuria, when treated by the reduction of the carbohydrates, return to normal, the blood pressure is reduced and the glycosuria disappears. I have seen three such cases and I believe that increased suprarenalism may be responsible for the high blood pressure and the glycosuria.

DR. F. M. ALLEN, New York: According to present evidence diabetes is not a disturbance of the suprarenal system. The glycosuria is not due to suprarenal stimulation. The vascular changes produced by epinephrin injections in rabbits are probably not a true reproduction of human arteriosclerosis. Many other agencies will produce such changes in the rabbit, which is a very susceptible animal.

Dr. Roussy failed to mention the important contribution of French authors to this subject, beginning in 1903. They established a relation of the chlorids not only to edema but also to high blood pressure. Salt restriction is the most effective means for the control of hypertension, and it has fallen into disuse and disbelief largely because of faulty application. It is seldom enough to tell patients to avoid salt, for most of them, even when conscientiously trying, will still get several grams daily, which will suffice to keep up the pressure in most cases. Before calling any case a failure, it is necessary, first, to give a genuinely salt-poor diet, containing less than 0.5 gm. of sodium chlorid daily; second, to make such a diet appetizing, so that the patient will eat it; and third, to control the treatment by blood and urine analyses to prove the efficiency of the chlorid restriction. Most such patients need treatment in an institution, to be treated and instructed as thoroughly as are diabetics, in order to obtain the best results. In this way some high pressures are brought to normal; some are altered very little or not at all; but the great majority of patients obtain some degree of relief. Cases of hypertension coming on about the menopause seem generally to be of the high chlorid type, and yield to salt restriction. Suitable tests may reveal the beginnings of some such cases long before the menopause, and study of the salt economy may prove important in relation to etiology and prophylaxis. A patient may have more than one disease, neither one dependent on the other. A woman had hypertension and myxedema. Her hypertension responded to salt withdrawal, and her myxedema to thyroid extract. Apparently the two conditions were independent. Many cases of combined metabolic disorders may perhaps be of this type. My longest observation of successful control of hypertension by salt restriction was fifteen months. Wherever good results have been obtained they have been permanent.

DR. W. S. THAYER, Baltimore: The actual physiologic cause of hypertension in most cases is by no means clear. Spasm of the peripheral vessels or extensive thickening of the small peripheral arteries is followed by hypertension, and that is all we know about it. The occurrence of associa-

tions is an important point to bear in mind. It will be very interesting to know the effect of treatment in the cases of hypertension, which Dr. Engelbach believes are due to disease of the glands of internal secretion, and how long such cases have been observed. Dr. Allen's observations with regard to the effect of salt-free diet are very interesting.

DR. WILLIAM ENGELBACH, St. Louis: Dr. Roussy referred to the relationship of the histopathologic changes of the suprarenal, the nervous system and other glands to the clinical syndrome of endocrine disorders. One must acknowledge that no such relationship has yet been established, owing, possibly, to difference of opinion among pathologists regarding the pathology of this disease. There exists a great deal of controversy among the French, who have contributed so much on the subject of internal secretions, that no positive deductions can be drawn from their work on the pathologic changes present in these diseases. Dr. Fishman's reference to arterial hypertension with epinephrin diseases does not correspond with my observations. In the great majority of cases there was a combination of glandular disorders, i. e., a pluriglandular syndrome. I can confirm Dr. Allen's statement that chlorid retention is responsible for a certain percentage of arterial hypertension but not for all high blood pressure cases. My position is much the same as his with relation to endocrine disorders being responsible for a small percentage of the cases of arterial hypertension; not, however, to the exclusion of many other well known causes. In the series of endocrine cases reported, we obtained good results with glandular therapy, without denying the patient a generous diet containing plenty of salt and allowing active exercise.

GOUT: A CLINICAL STUDY OF ONE HUNDRED AND SIXTEEN CASES*

CHARLES SPENCER WILLIAMSON, M.S., M.D.

Professor and Head of the Department of Medicine, University of Illinois College of Medicine

CHICAGO

The analysis of the present series of cases was undertaken because of my conviction that few diseases that are capable of being easily and accurately diagnosed are so often overlooked, or rather misinterpreted, as gout. Among well trained men gout is still too often a curiosity, rather than a clinical entity to be encountered and recognized. With the desire of centering the attention on this fact, the present study was undertaken.

Our series consists of 116 cases, which includes the material of the Cook County Hospital for approximately six years. At the very outset it may be remarked that a perusal of the histories leaves no doubt that the diagnosis of gout was made only when the clinical picture was such as practically to compel that diagnosis. I am well aware that in some quarters the diagnosis of this disease is made very lightly, notably at some health resorts; but the reverse is the case in this series. All were clear-cut cases about which, once the diagnosis had been thought of, there could be but little difference of opinion among experienced clinicians. My own belief is that a very considerable number of cases in the hospital go begging for a diagnosis. This is particularly true when patients are sent by mistake to the surgical wards. I have carefully checked the diagnoses as made at the examining room when the patients were admitted to the hospital. In general these diagnoses are exceedingly good, and it is remarkable at times with what

* Read before the Section on Practice of Medicine at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

acumen the house physicians detect really difficult cases; yet of our 116 patients, only twenty-nine were admitted as having gout or even suspected gout, despite the fact that sixty-five of them had the diagnosis written on their ears in unmistakable characters.

The conclusion is to my mind inevitable: Our younger clinicians are not on the lookout for gout, and as a result many cases are escaping us. Nor is it only the mistake of the inexperienced, for I can recall one patient who returned to the hospital on five different occasions at intervals of perhaps a year, before the correct and really very obvious diagnosis was made. Another patient was operated on in a surgical ward for an "infected hand" and the finger amputated, and the mistake never discovered until his next visit to the hospital a long time afterward. Still another patient left the hospital rather than be operated on for a "bunion," which a later stay in a medical ward showed to be an ordinary gouty toe. Indeed, this mistake was repeatedly made. Still a third patient had a knee opened and scraped, and several years later a finger operated on, with the diagnosis of infectious arthritis.

Our series labors under one disadvantage in that our patients came from the poorer classes who seek admission to a public hospital. It can, therefore, give no information as to the relative frequency of gout in the poor and in the well-to-do classes, since ours were largely cases of the so-called "proletarian gout."

It is rather remarkable that only five of 116 entered the hospital in their first attack, the great majority of our patients having been admitted many years afterward. This is quite in line with what is seen in our hospital in other similar diseases, the patients rarely seeking relief until the disease has been of considerable duration. As the early attacks of gout generally last only a short time, followed by a long period of well-being, the patient puts off seeking hospital aid. Over and over again we find that on asking the patient, who on admission has six or eight joints involved, whether he has ever had anything like this before, we receive a negative answer. A direct question elicits the fact that he had a painful swelling in the great toe five years before, which he has not in any way connected with his present trouble. Further questioning elicits the fact that he has had repeated attacks of so-called "rheumatism." It is surprising how rarely the patient recognizes the identity of the toe infection with the subsequent enlargement of the larger joints.

RESULTS OF OBSERVATIONS

Incidence.—Futcher gives the incidence of gout for Johns Hopkins as 0.29, and states that this is just two-thirds that of St. Bartholomew's in London, which would be 0.435. In our hospital the ratio of admissions from gout to the total admissions to the medical service is 0.399, which approximates very nearly that of the London hospital.

Etiology.—The influence of sex is by far the most striking fact observed in that only one case occurred in a woman, an incidence of less than 1 per cent. The influence of age is best seen by arranging the cases in decades, it being understood, of course, that this refers to the age at first attack. From 0 to 10, no cases; from 10 to 20, no cases; from 20 to 30, 15 per cent.; from 30 to 40, 37 per cent.; from 40 to 50, 29 per cent.; from 50 to 60, 18 per cent.; from 60 to 70, 1 per cent. The average age at time of first attack was 38 years. The interesting fact elicited is that 15 per cent. of our patients developed their first attack before their thir-

tieth year. This is rather opposed to the idea that gout is exceedingly rare before 30 or 35.

Nativity.—America leads with 47 per cent.; then come Ireland with 17 per cent.; Germany, 13 per cent.; Scandinavia, 7 per cent.; Austria-Hungary, 6 per cent.; Italy, Russia, France and Canada, each 2 per cent., and Belgium and England, each 1 per cent. In the population of a hospital, the cosmopolitan character of which is surpassed by few, it is rather noteworthy that not a single case appeared in a Pole, despite a very large number of Polish patients. The influence of race is shown in the fact that all of our patients, except two, were white.

Seasonal Influence.—This is quite pronounced. Of 126 attacks occurring in our 116 cases, we find the incidence as follows: January, 9; February, 6; March, 14; April, 20; May, 16; June, 11; July, 9; August, 3; September, 5; October, 8; November, 12; December, 13. Grouping these by seasons, we find that the spring months easily lead with fifty cases (40 per cent.); the winter months next with twenty-eight (22 per cent.); the fall next with twenty-five (20 per cent.), and the summer last with twenty-three cases (18 per cent.). It is exceedingly difficult to form an accurate idea in regard to the reasons for this predominance of the cases in the spring months. In some years it is much more striking than in others. I have not been able to trace any relationship between weather conditions and the frequency of attacks. A month of atrocious weather will go by without a case, followed by a week of beautiful balmy weather which may bring in four or five cases. There is, moreover, no uniformity in regard to an individual case. One patient had his attacks invariably in November, another invariably in autumn and winter, while another patient had seven different attacks in seven different months. Several patients noted that their attacks were ushered in by cold, damp weather, particularly if they got wet. In one patient the first attack was brought on by prolonged wading while on a fishing trip.

Heredity.—In our series only twelve gave any history of joint conditions in the family, and in several of these the condition was probably not gout. While it is undoubtedly true that patients in a charity hospital are less likely to have accurate information in regard to this point, especially if they are foreigners, than would private patients, it is my belief that these figures are substantially correct. In all the cases in which I have questioned the patient on this point, heredity was an insignificant factor.

Occupation.—The occupations were analyzed particularly with reference to the influence of lead poisoning. In only eleven instances (9.4 per cent.) was the occupation such that the patient had to deal more or less with lead. In none of the cases did lead seem to have been an actually demonstrable etiologic factor; that is to say, in none of them was there an outspoken plumbism present, as evidenced by colic, lead line on the gums, etc. The great majority of the occupations were those requiring hard manual labor.

Alcohol.—On the other hand, the influence of alcohol was very striking. Only four patients stated that they drank no alcohol or in negligible quantities. In nine cases the patient consumed a small amount of alcohol daily; forty-one others declared themselves to be moderate drinkers, while the remainder were heavy drinkers, some to great excess. No difference could be noted in those who consumed only beer and those who

drank whisky by itself or in addition to beer. The latter condition of affairs was the common one.

Trauma.—The influence of trauma has been much discussed, but in our series we were not able to determine that it was of influence in even a single case. I myself have seen several cases in private practice in which the patient stated that the attack was occasionally ushered in by stubbing the toe or by stepping down from a wagon or something of this sort. A closer analysis of these statements leads me to believe that the patient has confused cause and effect. By this I mean that in most instances the patient's attention is drawn to his toe because it is already inflamed, rather than the reverse.

Syphilis.—The incidence of syphilis is not so frequent as might have been expected among patients of this character, as it occurred in slightly less than 15 per cent. of the ninety-one cases in which it was specifically mentioned. A comparison of the ages at which they had the initial lesion with the age at the first attack of gout shows that in 4 per cent. the gout antedated the syphilis, leaving 11 per cent. of cases in which syphilis might conceivably have been an etiologic factor. The average duration of the syphilis at the time of the first attack of gout was sixteen years. In only one of these cases was there found any clinical evidence of the existence of syphilis, such as aortitis, tabes or skin rashes.

Overeating.—It is worthy of note that in a class of patients in whom want and privation might be reasonably supposed to play an important rôle, we find no evidences of this in our series. In 101 instances in which the condition is specifically noted, we find ninety-two patients noted as well nourished, and in most instances well built. Eight were fairly well nourished and only one poorly nourished. These figures are all the more striking in view of the statement made in many of the histories that the patient had lost considerable weight just before entrance to the hospital. We are to interpret these findings, therefore, as showing very decisively that the big, well-developed, portly individual is the one who develops gout, and this, too, in a population which is normally none too well nourished. The fact must not be lost sight of that the influence of alcohol may here be of moment, in that when we read that a man has been accustomed to drink a quart of whisky or twenty or thirty glasses of beer daily, the food value contained in these drinks is very considerable.

Nephritis.—The theoretical importance of nephritis in connection with gout is of course very great, and all the more so in view of the importance of recognizing a renal gout. Of our 116 cases, fifty-two (45 per cent.) showed albuminuria. In only seven instances was a nephritis thought to be of sufficient importance to make it part of the diagnosis, and in no instance was it ever recorded as a primary diagnosis, nor had any of the patients been in the hospital previously for a nephritis. In twenty-two instances the coexistence of albuminuria with a blood pressure definitely, but not greatly, above the normal for the patient's age made the beginning of a contracted kidney at least possible, perhaps probable. It would seem clear from our figures that in spite of the many cases of albuminuria there were relatively few cases of true nephritis.

Clinical History.—First Attack: In five instances the patient entered the hospital with his first attack of the disease. In only one were there any prodromal symp-

toms, these consisting of chilly sensations and cough. The onset in all was acute, with intense pain in the affected joint, which was in the great toe in three cases and the instep in two. The pain is described in all as intense, and in one so great that the patient "rolled around in agony." The joints were moderately swollen in all of them, and red and hot. The fever is noteworthy in that the average was only 100.3 F. One of these patients is in the hospital at the time of writing, and it is remarkable how much inflammatory change exists in the toe and how intense is the suffering as compared with the trifling rise in temperature. One patient had been ill for four weeks before admission, and in addition to this spent twenty days in the hospital, which is the best evidence of the severity of the attack. The remaining four patients averaged three days' sickness before entering the hospital, and remained in the hospital on an average of two weeks. One of these patients had outspoken nephritic symptoms with beginning broken compensation with this, his first attack of gout, and this case we have reckoned as our only case of probably true renal gout. In only one of these first attacks were any other joints than those of the foot involved. In this particular patient both knees were attacked. The remarkable feature of these first attacks is their uniformity, each case being almost a replica of the others.

Subsequent Attacks: The same uniformity exists in those patients who came in for second or subsequent attacks. These patients, 111 in all, form the entire series, with the exception of the five just discussed.

As there is generally a lapse of some years between the first and subsequent attacks, it was not always possible to determine with certainty in what joint the disease began. As a matter of fact, the average time that had elapsed between the first attack and the entrance of the patient into the hospital was ten years, since the average age at entrance was 48 years, and that of the onset of the disease 38 years. In 88 per cent. of our cases in which the joint first affected could be definitely determined, this was in the great toe, and it is noteworthy that the right toe was involved a little more than four times as frequently as the left. The small toes were involved by themselves once, the ankle and instep five times, the left thumb once, and the left knee once. It is equally striking that in those cases in which the disease began in some other joint than the great toe, it showed a strong tendency to attack that member later on. In our series this was the case to such an extent that 95 per cent. of our patients had the big toe involved sooner or later, leaving only 5 per cent. that had never had the big toe involved.

The great majority of the patients developed the attacks at night and with great suddenness. A few noticed the pain and swelling coming on in the daytime, and we note that when this is the case it comes on during the day in subsequent attacks.

Four cases were definitely polyarticular in their first attack. Because of the difficulty in the diagnosis of these cases, I shall give them a little more in detail. In the first case, both ankles, both big toes, the left knee and the index finger of the left hand were simultaneously involved; in the second, the hands and feet were affected; the third was unfortunate enough to have the right foot and instep, the right knee, the right hand, the left shoulder and the left foot simultaneously involved; the fourth showed swelling, redness and pain of the right ankle, right knee, left knee and the little and middle fingers of the right hand, and the middle

finger on the left hand. In all of these, tophi were subsequently found in the ears, and in two of them, sodium biurate crystals in the joint fluid.

These cases which are polyarticular from the very beginning should be sharply differentiated from the ordinary case, which begins in the toe and perhaps remains limited to the toe, or to the toe and instep for several attacks, and then, as these become more numerous, the number of joints involved becomes greater, and this to such an extent that 106 of the 116 cases became definitely polyarticular in the further course of the disease. The hospital physician who, for the most part, sees the case only after many attacks, is thus confronted with a picture of six or eight joints simultaneously involved. This fact probably accounts for the many times the disease is diagnosed as acute articular rheumatism. It is remarkable how little elevation of temperature is usually present, the average maximum of our series being 100.3. This we regard as of the highest diagnostic significance, since there are few clinical pictures in which a half dozen joints are greatly swollen and reddened which exhibit so little fever.

As compared with the descriptions given by most authors, the majority of our cases seem of unusual severity. The average length of attacks was twenty-nine days, some covering several months.

Tophi were present in sixty-six instances (56 per cent.). They were present in the ears sixty-five times, and in only one case were tophi found elsewhere without the ears being simultaneously affected. This case was in the great toe, producing a bunion-like deformity. In fourteen instances there were tophi in the ears and in other portions of the body as well. Such other locations were the fingers, toes, knuckles, thumb, elbows and the thyroid cartilage. Bursae were found four separate times, three times over the olecranon and once over the acromion.

The blood findings in our cases were quite uniform. A moderate leukocytosis occurred in most of the cases. The highest count that we have recorded is 19,800; the average count is 10,500. The average differential count was: polymorphonuclear neutrophils, 74 per cent.; lymphocytes, 14 per cent.; large mononuclears and transitionals, 11 per cent.; eosinophils, 1 per cent. The blood pressure, as would be expected from what has been said in regard to nephritis, was somewhat higher than normal, and averaged 147 systolic.

One frequently sees the statement that after an attack of gout the patient generally feels better than before. While this may be true in certain cases, we could not determine that it was true in any considerable number of our series.

The Roentgen Findings.—In forty-two of our cases, careful roentgen-ray studies were made of the joints involved. Fourteen of these cases were reported by the roentgenologist as either showing definite gouty changes or else changes that were consistent with gout. All of the other twenty-eight cases were returned with the statement that the joint changes indicated hypertrophic osteoarthritis, or else showed arthritic changes of an indefinite character. Of the fourteen cases recognized by the roentgen ray as gout, thirteen showed tophi in the ears, and the fourteenth patient had a gout of fifteen years' standing. Of the twenty-eight cases in which the roentgen findings were not characteristic of gout, twenty-one showed tophi in the ears. Now it is very evident that all of these cases were far

advanced, and the conclusion, therefore, seems inevitable that even in the most skilled hands, the roentgen ray is of very little service from a diagnostic standpoint. Long before the roentgen-ray findings are sufficiently definite to warrant a conclusion, the diagnosis can be made by the usual clinical means. Conversely, the roentgen ray in nearly two thirds of all the cases submitted to it not only failed to assist in the diagnosis, but tended, if anything, to lead one to arrive at wrong conclusions. We may not, therefore, give the roentgen findings a very high place in the diagnosis of gout, since the changes are not sufficiently characteristic to enable the differentiation to be made between it and kindred joint affections.

Association with Other Diseases.—The two classical diseases of metabolism associated with gout are, of course, obesity and diabetes. We have already noted under the etiology that the great majority of our cases were well nourished. In addition to this we find eleven instances in which the patient was spoken of as directly obese, and in a few instances the obesity attained considerable proportions. This was particularly true among the heavy beer drinkers. On the other hand, not a single case in all the series showed sugar in the urine at any time.

The abarticular forms of gout were almost nil in this series. One patient died of angina pectoris while in the hospital. A severe sore throat preceded the onset in five cases, and this further increased the resemblance to acute rheumatic fever.

CONCLUSIONS

The frequency of gout under our conditions is much greater than is commonly thought. Errors in diagnosis are relatively numerous, owing, not to the inherent difficulty in the recognition of the disease, but to the erroneous assumption of its great rarity in this country.

25 East Washington Street.

ABSTRACT OF DISCUSSION

DR. WALTER L. BIERRING, Des Moines, Iowa: Analyzing the report given in this excellent paper, one wonders that there are not local conditions or other influences which may explain this apparent increase in the number of cases. The cases are attributed largely to the incidence of good nutrition, or apparently good nutrition. Yet in many communities in which that obtains there is no gout, so that there must be something in the mode of life in a large city, of the class of patients that come to a large charity hospital to account for the greater frequency of these cases in the hospitals of the larger cities. With the clinical symptoms usually so well marked it is rather strange that the condition should be overlooked. An explanation may be found in the fact that we have been greatly interested in focal infections as causes of arthritis and have overlooked entirely, in a way, those cases of arthritis which were not due to infection. Furthermore, it occurs in single joints in many instances, and recurs frequently in the same joint; therefore, these patients are referred to the surgical service and the surgeon, not being on the lookout for tophi, overlooks the condition. Little evidence of infection, low fever and the involvement usually of single points, ought to make the diagnosis comparatively easy. The roentgen ray is practically a negative factor in the recognition of gout. Whenever there are distinct joint changes, the case most likely is one of arthritis deformans. We must rely on the appearance of tophi, and unless tophi are present we will always be in some doubt as to the existence of gout.

SIR HUMPHRY ROLLESTON, London, England: In London there seems to be no doubt that gout is commoner in people

who are brought in contact with lead than in other people. In other industrial centers where lead poisoning is common, such as Newcastle on Tyne, gout is rare. The importance of lead gout was insisted on by the late Sir A. B. Garrod. It is generally believed that the connection between lead and gout depends to a certain extent on whether the patient takes beer or not. Trauma may act in two ways, by predisposing to the attack in the big toe joint, and also by once determining an attack. Thus, after an undoubted injury, such as the falling of a box on the foot, a gouty patient may in a day or two have an acute attack of gout in that joint, and other joints may suffer in that attack. In connection with the diagnosis between arthritis deformans and gout, the two may be combined, as was shown at the Cambridge experimental hospital. Lastly, to refer to a rather dangerous subject, that of abarticular gout: There is a distinct tendency to regard almost any manifestation occurring in a gouty person as gout; for example, gouty bronchitis, the gout going to the stomach, and even cerebral gout; and the diagnosis of gout and goutiness may easily be much abused. I would suggest, however, that the question of abarticular gout should be taken seriously into consideration. Gout is recognized as a disturbance of protein metabolism, and the manifestations of anaphylaxis are now well known; gouty patients are extremely susceptible to various articles of diet; in other words, a gouty person may present symptoms analogous to those of anaphylaxis. Therefore, gouty manifestations, although they are entirely different from frank articular gout, may be due to the same change of metabolism as occurs in gout, and from a practical point of view may react to the treatment proper for gout. Not very long ago I saw a man with high blood pressure and the subject of gout, in an attack of what appeared to be undoubted hemiplegia due to cerebral hemorrhage. For some hours he was extremely ill. Then an acute swelling of the big toe joint came on, and the symptoms rapidly improved. I agree with Dr. Williamson as to the association of pharyngitis with gout; a gouty person may very easily, as a result of some indiscretion, get an attack of pharyngitis, or sore throat, which is relieved by antigout remedies.

DR. ALEXANDER LAMBERT, New York: Gout is not of infrequent occurrence in the eastern area of the United States. I have noticed that these patients have an English or Irish ancestry more often than not. A remarkable fact brought out by Dr. Rolleston is the peculiar idiosyncrasies of gouty people, appearing in different members in the same families. I have known a man who could not touch white wines, while his brother could not touch red, and still another member of the family could not touch any alcohol. In other members of the family an attack was brought on by coffee. Food idiosyncrasy has much to do with the production of gout. A peculiarity of a gouty joint is that the point of maximum intensity of pain is on the side of the joint, not on the top, and less frequently on the bottom. The point of greatest tenderness is almost invariably on the side. Chronic gout is a disturbance of protein metabolism. One of the best remedies is iodine or the iodids, which stimulate the thyroid. The dry skin, the chipping nails and the dry hair are manifestations of hypothyroidism. I believe the thyroid has more to do with gout than any other gland. The patients whom I have treated on the basis of thyroid deficiency have done better than those whom I treated on any other basis.

DR. CHARLES SPENCER WILLIAMSON, Chicago: Any arthritis which involves the great toe, either as the first joint or simultaneously with some other joint, should be regarded as highly suspicious of gout. Garrod's observation was not only thoroughly sound, but, if anything, fell short of the truth. An important diagnostic feature is the relatively slight fever, at times none at all, taken in connection with the great acuity of the local symptoms. This is not a new point, of course, but I do not think that it has found its way into the general clinical consciousness of the medical profession. When you are called to a patient, especially if a middle aged man, and find him with both knees, an elbow or two, and at the same time the great toe greatly swollen, with a temperature of, perhaps, 99 F., do not forget to think of gout before any-

thing else. By the time the case has reached this stage tophi are generally present in the ears, but they must be looked for with real care, as the diagnosis may depend on a little nodule in the ear scarcely as large as a small pinhead. I was very glad to hear Dr. Lambert bring out the point about the pain on the side of the toe. Less than ten days ago I called the attention of one of my interns to that point, but as far as I know it is new, and I was not sufficiently assured of the accuracy of my observation to be sure that it was of diagnostic importance. I have noticed half a dozen times that the pain is almost entirely on the side. I did not quite have the courage to bring that out. Let us rid ourselves of the idea that gout is a disease of extraordinary rarity in this country, since the incidence in general hospital practice is not much less than in a London hospital of the same general type.

A CLINICAL STUDY OF THE END-RESULTS OF SOME FOCAL INFECTIONS *

BRYCE W. FONTAINE, M.D.

MEMPHIS, TENN.

In a casual survey of the literature on focal infections, one is impressed with the fact that only recently has the subject been studied from the standpoint of its bearing on systemic disease.

Until the last decade there were few notable contributions. In 1819, Rush reported the cure of a case of rheumatism by the extraction of a tooth. William Hunter, in 1899, recorded his studies of what he termed "oral sepsis." Later, the dentists Price, Broomell and Chayes in their articles cautioned against careless dentistry and neglected oral sepsis, suggesting the probability of systemic disease ensuing. Goadby's article in 1912 claimed the direct relationship of some joint conditions to focal infection.

It remained, however, for Frank Billings and his co-workers, especially Rosenow and Davis, to bring the subject prominently before the medical profession. Too much cannot be said in praise of their work, and the credit for the present knowledge of the subject must be given to them. Since the first paper by Billings appeared in 1912, tremendous enthusiasm has been manifested in this subject, many articles and one monograph appearing within the short space of eight years.

Despite this splendid work, there exists in many sources some doubt as to the part focal infections play in the production of diseases, and many are questioning whether or not any real relationship exists. A warning is sounded lest we, in our zealous efforts to eradicate suspected foci, sacrifice useful organs, such as the teeth and tonsils. I realize that in many instances the pendulum has swung too far, and that some practitioners are likely to remove sound teeth or tonsils without justification. If the cases are carefully studied from every angle, and all other possible etiologic factors eliminated, the prompt relief obtained by radical measures should convince the most skeptical that it is not due to accident, coincidence, or to any effect on the mind.

In this confused state of evidence, it may be of interest to hear the clinical experience of one observer, and note the end-results obtained in approximately 100 cases selected from a private and consultation practice, during a period of two years.

* Read before the Section on Practice of Medicine at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

The relation of the focus of infection to the symptoms in question has depended on: (1) the absence of any other demonstrable cause for the symptom; (2) the failure to cure the symptom by all other methods of treatment, and (3) prompt and continued relief, with no return of the symptom, on the cure or eradication of the focus of infection.

In this study, conclusions have been arrived at largely through the cooperation of a group of nose, throat and dental specialists. Great reliance has been placed on roentgenograms of the diseased structures.

SOURCES OF INFECTION

The teeth have been the most common source of infection, and all varieties of dental conditions, from pyorrhea to unerupted twenty-one year molars, have been encountered. The most common lesions were either apical abscesses or granulomas at one or more roots of devitalized teeth. The diagnosis was confirmed by plates of the whole upper and lower jaws, including all devitalized teeth. Not only should infected teeth be removed, but the cavities left should be thoroughly curetted.

The tonsils were next in importance as a seat of infection. The small fibrous, or submerged, tonsils were quite as frequently involved as those visibly infected and greatly hypertrophied. Complete enucleation with the capsule was usually necessary for permanent relief.

The sinuses were least in importance in this series. The maxillary sinus was most frequently implicated, because of its close proximity to the throat and nose. Transillumination and roentgenograms were employed to reveal existing trouble.

There has been no experience with foci of infection in other parts of the body. Billings, however, reports them in almost every conceivable location.

SYMPTOMS FOR WHICH RELIEF WAS SOUGHT

Pain occurring in 42 per cent. of the cases was the symptom for which relief was most frequently sought, the location usually being in the muscles of the neck, back, chest or limbs. In a few cases it occurred along the course of some nerve, frequently branches of the brachial plexus or the sciatic nerve. Its character varied from ordinary discomfort to intense agony, requiring morphin for alleviation. The painful area was not affected by changes in temperature, nor was it often associated with tenderness. It was not accompanied by fatigue, or other neurotic symptoms one might expect in neurasthenia. Conditions about the teeth most frequently produced these symptoms, though some cases were due to diseased tonsils or sinuses.

CASE 1.—E. A. S., a white man, aged 50, had constant pains in the right back, side and hypochondriac region, at times severe enough to require morphin. A diagnosis of gallstones had been made, and operation advised. A physical examination of the chest and abdomen was negative. The gastric contents, urine and blood were normal. The Wassermann reaction of the blood serum was negative. Only temporary relief was obtained by the usual methods of treatment. Examination of the teeth disclosed two apical abscesses. Removal of the teeth afforded immediate relief, with no recurrence of pain.

CASE 2.—H. C. N., a white man, aged 35, had pain in both shoulders, causing discomfort, rather than acute suffering. It was not especially related to the joints or nerves, but affected the muscles about both shoulders. There was no tenderness. It was not affected by changes in weather. Physical examina-

tion of the heart, lungs and abdomen was negative. The urine and blood were normal. The Wassermann reaction of the blood serum was negative. Examination of the throat revealed infected tonsils. The patient was always relieved for weeks at a time, by massage and squeezing out of crypts by a throat specialist. Ordinary methods afforded no relief. Tonsillectomy was finally performed, giving immediate relief, with no recurrence of pain. The patient made a gain of 12 pounds.

Fever, occurring in 18 per cent. of the cases, was second in importance as a symptom. The fever, seldom over 101 F., was not often accompanied by chills, though in a few cases night sweats occurred. These cases were usually ambulatory, resembling, and most frequently confused with, the fever of incipient tuberculosis. The foci were about equally distributed between the teeth and the tonsils.

CASE 3.—H. R. W., a white man, aged 44, had had fever for four weeks, with some malaise, an occasional night sweat and a slight loss of weight. His highest temperature was 99.8 or 100, usually in the afternoon. The patient was not ill enough to go to bed. He had been at his office almost every day. Physical examination of heart, lungs and abdomen was negative. The differential blood count was normal. There were no plasmodia. On three occasions the Widal test was negative with typhoid and paratyphoid bacilli. The Wassermann reaction of the blood serum was negative. There was slight tenderness about the first lower molar on the right side, which was devitalized and crowned a few years ago. A roentgenogram revealed an apical abscess. Removal of the tooth was followed by prompt and permanent subsidence of temperature, with a gain in weight to normal.

Chronic headache as a result of focal infection has long been suspected by throat and oral surgeons. Often in their experience the removal of infected tonsils has relieved the patient of headache of long standing. In this series, chronic headache has occurred in 4 per cent. of the cases, each depending on tonsillar infection. In every case a prompt and permanent cure has followed tonsillectomy.

CASE 4.—Mrs. W. V., aged 28, white, complained of headache, which had occurred rather frequently for the last two years. It did not occur at any regular time, nor was it related to the menstrual period. The patient had had no previous illness. She had had many examinations, with negative findings and no benefit. The last physician who made an examination suggested glasses, but they caused no improvement. Physical examination of heart, lungs, abdomen and pelvis was negative. Neurologic examination was also negative. The urine, blood and gastric contents were normal. The Wassermann reaction of the blood serum was negative. An oral surgeon reported that all sinuses were negative, but the tonsils were hypertrophied, showing evidences of infection in the crypts. Tonsillectomy gave prompt relief.

General debility with loss of weight and strength, resulting from focal infection, has occurred in about 10 per cent. of the cases.

This syndrome, as a rule, occurred in middle-aged adults, without any other apparent basis, and in most instances was accompanied by obvious diseases of the teeth. No cases have occurred with infection elsewhere. In many cases it was necessary to remove all the teeth in order to get rid of the severe oral infection, all ordinary methods of treatment having utterly failed. Removal of the teeth and treatment of the gums, when promptly and effectively done, was followed by marked improvement in the general condition, with a gain in weight and strength.

Severe secondary anemia occurred in 4 per cent. of the cases. In no case, despite the ordinary methods of treatment, such as rest, feeding and the continued use

of iron and arsenic, was there any perceptible improvement until the removal of the focus of infection. The cases were equally distributed between the tonsils and the teeth. In no instance did the blood present the morphologic appearance of pernicious anemia. There was usually a moderate reduction of the hemoglobin and in the number of erythrocytes, with normal differential and leukocyte counts.

CASE 5.—Mrs. N. O. E., aged 26, white, complained of weakness and indigestion, beginning more than a year before. Physical examination of the heart, lungs, abdomen and pelvis was negative. The Wassermann reaction of the blood serum was negative. The urine was negative. The gastric contents after an Ewald test meal showed free hydrochloric acid 5, total acidity 16. Blood examination revealed: leukocytes, 7,300; erythrocytes, 3,800,500; hemoglobin, 65 per cent. Differential count revealed: polymorphonuclears, 63 per cent.; transitionals, 1; lymphocytes, 29; large mononuclears, 5; eosinophils, 2. Red cells were slightly irregular in size. No normoblasts were seen. There were no plasmodia. Examination of the throat by an oral surgeon showed the tonsils to be hypertrophied and infected. Tonsillectomy resulted in an almost immediate gain of 12 pounds. Four months later the blood was normal.

The relationship of focal infections to albuminuria and nephritis has been proved and referred to by several observers, prominent among whom are Ophuls, Klotz, LeCount and Jackson. In this series there were six cases apparently dependent on this cause. In a majority the focus of infection was in the tonsils, though in two, it was about the teeth. In every instance, after tonsillectomy or removal of the oral infection, there was a progressive improvement, with a disappearance of albumin and casts from the urine.

CASE 6.—Mrs. W. L. S., aged 32, white, complained of aching, loss of weight, and pain in the back and shoulders. Physical examination of the heart, lungs and abdomen was negative. The blood was negative. The systolic blood pressure was 110, the diastolic, 80. The urine showed a moderate trace of albumin, with numerous hyaline and granular casts. After a Mosenthal test meal for renal function, the urine showed a total output of 1,240 c.c., a normal variation in the specific gravity of day specimens. The specific gravity was inversely proportional to the volume of the specimens. There was diuresis after the first two meals; after the third meal, it was very slight. The night urine was small in volume, with high specific gravity. There was adequate salt elimination, and adequate nitrogen concentration in the night specimen. There was moderate fluid retention, and slight nitrogen retention. The salt concentration was low. The phenolsulphonephthalein output at the end of two hours was 30. The tonsils were small and fibrous, showing pus in the crypts. Treatment by dieting and rest for some months resulted in no improvement. Tonsillectomy eight months ago gave immediate relief from pain, with a gain of 20 pounds. The urine three weeks ago was absolutely normal.

The association of achylia gastrica with focal infections has been referred to by several observers, cases being reported by Beck and others. Every gastroenterologist has witnessed the improvement in many cases of this character, following the cure of oral sepsis. In this series there were six cases, all proved by the fractional method of analysis to be true achylia. In each there seemed to be considerable infection in the mouth, but in no other location. In some of the cases the extent of the infection necessitated the extraction of all the teeth. Without exception, improvement followed the cure of the oral sepsis. Free hydrochloric acid reappeared to some extent in every case, and in a few it finally reached the normal level.

CASE 7.—Mrs. E. T., aged 38, white, complained of loss of weight and strength, discomfort in the abdomen, gas and constipation. Physical examination of the heart, lungs and abdomen was negative. The blood and urine were negative. The Wassermann reaction of the blood serum was negative. The gastric contents by fractional analysis showed a total acidity of 12 at the end of one and one-half hours. There was no free hydrochloric acid throughout the test, which was carried on for two and one-half hours. There was no occult blood or lactic acid. Roentgenographic examination of the stomach, after a barium meal, was negative, except for hypermotility, the stomach being empty at the end of three and one-half hours. The patient had previously had several attacks of tonsillitis. The tonsils were recognized to be hypertrophied and infected. Under dieting and free hydrochloric acid, along with a modified rest cure, there was only slight improvement. Tonsillectomy was performed eight months ago, with immediate improvement in the patient's general condition, with a gain in weight and strength, and improvement in stomach symptoms. The last analysis of gastric contents, one month ago, showed free hydrochloric acid 12, and a total acidity of 20.

Vascular hypertension of moderate degree, indicated by a systolic pressure of from 150 to 170, occurred in 6 per cent. of the patients, all middle-aged persons, principally women. In these cases the condition was apparently not due to nephritis, because of the negative urine findings. There may, however, have been some chance of error, if we consider as a clinical entity the hypertension of the climacteric so well described by Reisman, and probably due to some endocrine dysfunction. In every case the hypertension seemed to resist all ordinary therapeutic measures, such as dieting, rest and vasodilators. Without exception, the infection was about the teeth, and on its cure there was a prompt reduction in the blood pressure, though it rarely reached normal.

While the report of the foregoing cases does not comprise all in which there has been a direct relationship or dependence on focal infection, others have occurred with rarity, and time forbids mentioning them.

Finally, a word must be said about joint conditions. No acute joint cases are tabulated in this series. There have been perhaps eight cases of chronic arthritis, usually of the type of arthritis deformans, with definite deformity and disability of many joints. An unsuccessful attempt was made to benefit these patients by curing foci of infection existing in the teeth, tonsils or sinuses.

CONCLUSION

While this report is necessarily brief, I hope it is sufficiently convincing to prove that often such conditions as pain, fever and headache are directly traceable to focal infections, and that the most effective measure for relief is complete eradication, or a cure.

Central Bank Building.

ABSTRACT OF DISCUSSION

DR. FRANK BILLINGS, Chicago: Focal infection as a cause of disease has come to stay. But, like every other principle in medicine, it has its limitations. Many of those who accept it have not thought of just what the term means. A focus of infection differs from a focal infection. A focus of infection may give rise to focal infection, or it may give rise to intoxication of the body. What is meant by infection? Infection means the invasion of the body by micro-organisms that have the power of reproduction in the host, of producing reactions within the tissues of the host, and the reaction producing abnormal phenomena, which we term clinical manifestations of disease. Focal infection means the invasion of the body

from a focus of pathogenic organisms, and these organisms have the power of reproduction or of multiplication within the host. Much of the fallacy and failure in the treatment or management of the patients who suffer from what may be proved to be focal infection is due to the fact that the surgeon or physician in charge removes a focus, which may be the right one, and then neglects any further management of his patient. And, if what I have just said is true, then the removal of the focus has not disturbed the organisms already in the tissues of the body. If you have removed the true focus, you have simply prevented the invasion of the tissues by additional organisms from the primary focus. Focal infection is usually an invasion by pathogenic agents of the tissues through the blood stream. They lodge in the tissues, they produce reactions, dependent on their character and on their virulence. They remain there if the defenses of the host are not sufficient to kill them or at least to drive them from the body. And unless, in the treatment of chronic infectious arthritis, for instance, that fact is borne in mind, the removal of the focus will usually not greatly benefit the patient, or at any rate not the majority of patients. Therefore, what is your duty? Our duty is to build up the resistance of the host against the invaders already there by all of the known means of support of the patient from the beginning of treatment. Can we use anything specific? The use of antigens in the form of dead bacteria, injected subcutaneously, in my experience, is not justified. I have used them all, controlling the work with all the knowledge we have, using the autogenous, the nonautogenous, the activated and the non-activated. The controls got along just as well as those that had the vaccines given them carefully. May one use some other specific? It is not uncommon now to read that a foreign protein antigen, injected intravenously, will restore the protective powers of the body, and drive out the pathogenic invaders. Apparently, many men have had success. But immunologists are not able to tell us much if anything of the *modus operandi*. It produces serious reactions, and we are using it in a haphazard way. The conscientious man is taking the health, and possibly the life, of the individual in his hands when he uses these substances. I do not say, do not use them, but I believe that we should approach that part of the treatment with judgment and discretion.

DR. JOSEPH H. PRATT, Boston: The subject of focal infections in its present day conception is very complex. There is much need of careful clinical study. Dr. Fontaine took a conservative position. A defect in most of the papers on this subject is that they give only the immediate results of removing foci of infection, but Dr. Fontaine has followed his cases for from one to two years, and the results are striking. I wish every physician in my section of the country could have heard the words just spoken by Dr. Billings, because the idea of focal infection, especially abscesses about the teeth, as a cause of chronic disease has spread like wildfire. At the present time many physicians, if they have an obscure case, simply advise the patient to go to a dentist and have the dead teeth removed. When this is done the patients are often turned adrift. Even living teeth may be extracted. The treatment in cases of psychoneuroses may consist simply in the extraction of teeth or of a tonsillectomy. Last summer I saw a woman with a mild neurasthenia, without a symptom of chronic infection, who was sent by her physician to an oral surgeon, who according to the patient's statement was the leading authority in the state. Fifteen teeth were extracted. I saw the roentgenograms later and only eight of the fourteen teeth were dead! Her symptoms became more marked after the teeth were removed. Many of the chronic cases that drift from physician to physician are patients suffering from psychoneuroses, and while it is proper, of course, to treat the teeth if they are in bad condition, it is a mistake to consider that in these cases the discovery and removal of infected teeth constitutes proper diagnosis and treatment. If an infection has become generalized, removal of the local focus will not result in cure. In a rare case of recurrent thrombophlebitis under my observation for several years there was chronic antral suppuration. Treatment of the empyema was followed by improvement for

about one year; then new thrombi formed. Careful examination has revealed no focus of infection outside of the inflamed veins, but every few months he has an attack of phlebitis with fever. Support from pathologists and immunologists is needed in solving the clinical problems connected with focal infection.

DR. FRANK B. WYNN, Indianapolis: In the olden days men were very prone in obscure cases to hide behind the liver; and a little later they found recourse in malaria to cover their sins of ignorance; and I wish to join with Dr. Pratt in emphasizing still further the point he made, namely, that the sin which we are very apt to commit at this time in regard to this matter of focal infection is that in cases with obscure symptoms we will hastily put the blame on the tonsils or on the teeth, without due clinical investigation of that case. It behooves us not to be content with looking at the tonsils or the teeth, but to search the body for other foci of infection. One other point is there which I wish to make, namely, that, granting the importance of a focus of infection, from which there is fed into the system the infectious material that gives rise in one case to rheumatic symptoms, in another to neuritis or to a neurosis, let us beware of the manner in which we proceed to correct that focus of infection. A patient had pain in the back, with tenderness, which was designated by her physician as lumbago. She unquestionably had bad teeth. On the advice of her physician they were extracted. In twenty-four hours following the removal of her teeth, she had severe pain throughout the whole extent of her spinal column, which rapidly developed into a typical spondylitis deformans. Undoubtedly, many of you have discovered bad tonsils, associated with the development of a chronic nephritis. You have removed the tonsils as the focus of infection, only to find that following the operation there has been an extreme aggravation of the symptoms, and in a few cases very disastrous results.

DR. W. S. THAYER, Baltimore: In dealing with many obscure conditions, looking for and properly treating a focus of infection, which may be a contributory cause of the trouble, we sometimes forget that our responsibility goes considerably beyond the point of finding a focus which may possibly be the seat from which the infection which has caused the trouble has come, and of considering its proper treatment. The attempt to treat these foci of infection properly has made common surgical operations which were not so common years ago; and it has brought into use certain specialties of surgical procedure which were not common years ago, surgical procedures of a very delicate character, which only the best trained man is capable of carrying out. I know many men whom I would be glad to have take out my appendix, if it were necessary. I know very few men who I would be willing to have take out an adherent tonsil or interfere with ethmoid disease. The proper treatment of ethmoid disease, and of gravely infected tonsils is often a serious matter. Those are very delicate procedures, which should only be done by very well trained surgeons. And there are relatively very few well trained surgeons in these special branches. It is our duty to consider very carefully to whom our patients are sent, and, furthermore, to follow them up afterward. The common treatment of the teeth in individuals whose trouble is supposed to depend on infection there is barbarous in the extreme. The reckless manner in which teeth are extracted today is a scandal to the medical profession. The very commonest infection in the mouth is probably gingivitis and pyorrhea alveolaris, which is not properly treated in the vast majority of cases. Very few dentists pay proper attention to pyorrhea alveolaris, and it is the duty of the physician to find one who does. I often do not know what to do when I have to refer a patient to some one for the treatment of such a condition. Dead teeth are opened and extracted on suspicion, simply because they are dead. Such a procedure is shameful. The extraction of a dead tooth, because it is dead, is unpardonable.

Often apical necroses are found in teeth, and those teeth are instantly extracted. In many instances that is an entirely wrong procedure. An apical necrosis does not at the moment often mean a very grave infection. Very often it is easy to

treat the condition without extracting the teeth. A sufficiently free opening, with curetting, and amputation of the root, done by a skillful man, will save many teeth which are today sacrificed recklessly. When we send a patient to a dentist to have his teeth extracted, it is not only necessary to see that he is properly cured, but it is unfortunately necessary very often to watch the patient to see that he himself treats the cavities properly. I know dentists of the highest reputation in their communities who extract a tooth, curet well the socket and then dismiss the patient; and I have on more than one occasion met such a patient several years later, and found that he had suppurating cavities, the necrosis still continuing, well closed in, simply because the cavity had not been properly treated.

DR. LEON L. SOLOMON, Louisville, Ky.: It were well for us, in searching for the primary focus of infection, to search the lower part of the gastro-intestinal tract, more particularly the lower part of the colon, the sigmoid and the rectum for a secondary, as well as for the primary focus. It has been my observation that the colon, the sigmoid and the rectum often contain an old focus of infection which is responsible for the means of ingress into the body of infecting organisms.

DR. CARLETON DEDERER, Bay City, Mich.: This subject is in the experimental stage. However, I want to place the weight of my influence on the side of the enthusiast rather

VIRULENCE OF DIPHTHERIA BACILLI FROM DIPHTHERIA PATIENTS AND FROM CARRIERS

THE RESULTS OF FIVE HUNDRED AND
FORTY-EIGHT TESTS *

AUGUSTUS B. WADSWORTH, M.D.

ALBANY, N. Y.

During the last four years we have found it necessary to test the virulence of cultures that have been obtained from convalescent and from contact carriers, and also those from a group of persons who have been classified as noncontact carriers. We have found these virulence tests helpful in distinguishing the nonvirulent from the virulent diphtheria bacilli, and thus have been able to authorize the release of patients when virulent diphtheria bacilli are no longer present in the secretions.

When the laboratory first undertook to make these tests, health officers and physicians were eager to send cultures in the hope of securing the release of their

* These noncontact carriers were carefully classified as carriers when there was no diphtheria.

† These noncontact carriers could not be so accurately classified.

than on the side of the conservative. My method of treating surgical patients consists in making a general rigid physical examination first. In all cases in which a major operation, such as a cholecystectomy, is done, I always, if the patient consents, eliminate the minor foci in the teeth and in the tonsils, if they appear to show infection, before I remove the other foci of infection.

DR. BRYCE W. FONTAINE, Memphis, Tenn.: The diagnosis of focal infection is made reluctantly, not until every other means of arriving at the cause in these cases has been exhausted, and then only with the cooperation of other men, who are conservative and especially skilled in their several lines. These end-results have been carried over two years, and during this time there has not been a return in one of the cases reported.

Clinically Trained versus Laboratory Trained Observers.

—Many valuable signs are only perceptible to the trained eye or the trained ear or the trained finger. Still more valuable signs are only revealed by the sensations experienced by the patient. To interpret these requires a training that can only be acquired by many years of patient observation, during which the mind is stored by the experiences of the past, by methods which are peculiar to medicine. These methods can never be acquired by a laboratory trained observer, and it is because of this that men trained in the laboratory fail as clinical investigators, however distinguished they may be as physiologists, chemists, or bacteriologists.—J. MacKenzie, *Brit. M. J.* 1:109 (Jan. 24) 1920.

patients or carriers from quarantine. In fact, they chose to send cultures to the laboratory for virulence tests rather than to undertake the strenuous task of getting the patients to rid themselves of the cultures by mouth-cleansing and other general measures of personal hygiene, all of which are either generally disregarded or are not very carefully carried out.

VALUE OF ROUTINE VIRULENCE TESTS

At first, the task of making these virulence tests was an arduous one. Nevertheless, tests were made during a period of two years with 250 strains of the diphtheria bacillus. To determine the value of these routine virulence tests, Dr. W. E. Youland, of the laboratory staff, tabulated the results. He found that 90 per cent. of the strains of *B. diphtheriae* that were isolated from cases of clinical diphtheria, from the day of onset to and including one year after onset, were virulent for guinea-pigs. Eighty per cent. of the strains isolated from a smaller series of healthy contact carriers who acquired the bacilli during epidemics were virulent,¹ while only 10 per cent. of the strains isolated from noncontact carriers were virulent. The noncontact

1. Diphtheria Carriers, New York State Department of Health.

carriers of this series were persons in state institutions or schools where there were no cases of diphtheria, who, nevertheless, carried diphtheria bacilli in their secretions. Ninety per cent. of the cultures that were obtained from convalescent patients during the first three months after the onset of the disease and from contact carriers were virulent. It was thus possible to discontinue a large part of the work, namely, the examination of convalescent and contact carriers during the first three months after the onset of the disease.

But physicians and health officers, who are deeply concerned for the release of their patients, have very naturally been impatient at this delay. In order to avoid making any unnecessary hardship for these carriers, it has been customary to make examinations whenever the health officer thought there were special reasons why he should have such a test made and stated his reasons clearly. Thus a considerable number of virulence tests have been made since the previous tabulation, and it is thought that it might be of interest to record the results of these examinations.

The tabulation of this series includes 334 virulence tests that have been made from January, 1916, to April, 1919. The classification of noncontact carriers is nondescript and not as reliable as that in the previous study of noncontact carriers on account of the fact that it was impossible to get complete and reliable information from all the physicians who sent these cultures to the laboratory. The results of this tabulation are presented in the accompanying table. The results obtained in the tabulation of the first series are included for the purpose of comparison.

When the results obtained with cultures from convalescent carriers in whom the duration of infection is less than three months are examined, it is found that of 147 strains of *B. diphtheriae*, 136, or 92.5 per cent., are virulent. This agrees closely with the results obtained in the first series, in which 90 per cent. of the strains were virulent. In the same period, from healthy contact carriers, twenty-eight strains of diphtheria bacilli out of thirty-five strains tested, or 80 per cent., were virulent; 80 per cent. was also obtained for these contact carriers in the first series.

The percentage of virulent diphtheria bacilli from convalescent carriers of more than three months' duration, 89.2 per cent., agrees closely with 92.5 per cent., obtained in cases of less than three months' duration. The number of examinations made on contact carriers in this period, nine, is too small to be of any significance.

CONDITIONS AFFECTING STATISTICAL VALUE OF RESULTS

The number of cases, 101, in which the duration of the disease was not stated on the information blank renders the results of these examinations for virulence unavailable for statistical study. Similarly, the results obtained for noncontact carriers are of little value since the information describing the cases as noncontact was often unreliable.

In both series, 398 cultures from convalescent and contact carriers in which the duration of the infection is known were studied. Three hundred and fifty-seven, or 89.7 per cent., of these were virulent. When the total number of tests for virulence (548) are examined without attempt to classify the cases on which the tests were made, it is found that 440, or 80.4 per cent., are virulent.

CONCLUSION

It is evident that *B. diphtheriae* from persons who have had diphtheria or from those who through contact become "carriers" retains its virulence for several months. Changes in virulence or changes in species or strains of the diphtheria organisms take place so slowly in the throat that the three months' period required before making these virulence tests is, after all, a lenient ruling and a satisfactory one if, in special instances in which carriers are definitely known to be noncontact carriers, a virulence test is made without delay.

ABNORMAL LACTATION

A CAREFUL STUDY OF THE LITERATURE, WITH THE REPORT OF A CASE *

M. J. SEIFERT, M.D.

Attending Surgeon, St. Mary's Hospital

CHICAGO

Lactation, the coping stone of motherhood, is a function sometimes impossible, often intentionally or ignorantly neglected, and in many instances practiced to excess.

In women of high social standing, the last mentioned condition is practically unknown. Investigations show that among women of the poorer classes, and particularly among the tribes and races of ignorant and uncivilized peoples, prolonged lactation is common. This is much to be regretted, as it tends to produce depletion of the mother with symptoms of "tabes lactealis," and poorly nourished babies.

TIME

Normally, nine months is considered the proper period for a mother to nurse her child. Under prolonged lactation would come cases in which maternal nursing, wholly or partially, has been indulged in longer than twelve months.

When lactation exceeds a period of two years, it is, however, permissible to speak of it as "abnormal mammary secretion," as the child, obviously at this time, has become independent of the milk supply of the mother; yet it is an altogether common occurrence to see lactation intentionally prolonged indefinitely, sometimes exceeding forty years (Cazeaux¹). In the ethnographic work by Ploss² we find that this unnatural custom is found among all the races of the globe. Gellhorn,³ in his travels in Siam, reports that he has repeatedly seen a boy of 6 or 7 interrupt his play, or put his palm-leaf cigaret behind his ear, and return to his mother's breast and take a sip of refreshment. Among the poorer classes this habit is often induced by economic reasons, but sometimes, also, as a matter of convenience, since it pacifies the child with the least disturbance to the mother. Then, the popular belief that lactation prevents conception is also a potent factor in producing this custom. Jacobi, many years ago, stated that "lactation and pregnancy are incompatible," but this statement is far from being universally accepted.

LACTATION AND CONCEPTION

Weinberg⁴ states that conception occurred during the first six months after childbirth in only 1.2 per cent. of 513 nonmenstruating women nursing their children, and in 59.5 per cent. in 615 who were not nursing.

Fordyce⁵ reports that out of 645 cases, 22 per cent. were cases of prolonged lactation. The same author⁶ states that overlapping pregnancy and lactation occurs in 24 per cent. of mothers, and may, obviously, exist for some time without being suspected. Only too often in such cases, it is found that after the birth of the child the mother is quite unable to nurse satisfactorily for any length of time, as the milk is usually poor in quality and insufficient in quantity.

Fordyce⁷ conducted an observation on 100 mothers who had given birth to 405 children (twins in five cases); of these, 376 infants survived at least two months. In 259 (69 per cent.), the children were nursed at the breast for at least two months, and therefore in these 259 cases there was a possibility of pregnancy or menstruation coexisting with lactation. In these cases the duration of lactation averaged ten months. In six cases the condition as to menstruation was not ascertained. Of the 253 remaining cases of lactation in which this point was determined, in 60 per cent., there was complete amenorrhea, while in 40 per cent. menstruation occurred.

From every point of view, prolonged lactation is unsatisfactory. The risks are real, and the compensating advantages only illusory.

I am emphatic in the belief that along with the constant reiteration of the command for maternal nursing there is the very important obligation of advising a strictly limited lactation. While my personal figures are comparatively small, my findings concur with those of other observers, and lead to the deductions that:

1. The concurrence of pregnancy and lactation is comparatively common.
2. Conception is rare within the first six months of lactation, and uncommon before the eighth month.
3. When pregnancy and lactation overlap, both the fetus and the mother are likely to suffer.

EFFECT ON BABIES

Fordyce⁷ studied 300 children with regard to rickets and prolonged lactation, and found that rickets was more common among children who were breast fed for over eight months than among other children. This he attributed to the natural variations in the composition of mother's milk, not only in different individuals, but in the same individual at different times.

While no one questions that, where practicable, maternal nursing, when properly regulated, is the best and only method of procedure for the good of both mother and child, one must, however, not lose sight of the evil consequences of overlapping pregnancy and lactation, and prolonged lactation. Such conditions foreshadow a diminished value of the milk in future lactations, and consequently form a serious handicap in the natural nutrition of later infants.

CAUSE OF PELVIC INFLAMMATION

Fordyce also reports that prolonged lactation is a cause of pelvic inflammations.

Walsh,⁸ who made an extensive study of prolonged lactation, states that the deleterious effects of this prac-

tice are more noticeable in women physically below par, and that they suffer from serious disturbances—circulatory, digestive and nervous; that the endometrium, as well as the muscular structures, partake of the general debility; that they suffer metrorrhagia from relaxation of the capillaries, and, that leukorrhea usually accompanies their other symptoms.

Lawson Tait asserts that prolonged lactation is the cause of a large number of cases of subinvolution of the uterus; and, further, that "in the majority of cases, one might almost say that in ninety-nine out of every 100 cases, chronic endometritis is accompanied by, and is indirectly due to, subinvolution of the uterus, following labor or miscarriage."

Skene mentions this as predisposing to endometritis, and reports a case of a woman who nursed her child for eighteen months and who, in consequence, suffered from cervical endometritis.

Thomas also mentions it as a cause of chronic cervical endometritis.

Marion Sims⁹ says that metrorrhagia may result from superlactation, but that such cases are not common and usually not obstinate. He mentions eight cases of metrorrhagia due to this cause. The period of suckling varied from sixteen to twenty-four months.

Johnston⁹ reports the occurrence of mammary secretion, accompanied by certain rational signs of pregnancy, in two nonpregnant women. One of these patients had retroflexion of the uterus. When this was corrected the secretion of milk ceased.

Stewart¹⁰ reports the case of a woman who was secreting milk from her right breast six years and four months after delivery. The child was not nursed on account of insufficient secretion and too short nipples. A plastic operation, and one for retroflexion, had been performed after confinement. The pelvic organs were otherwise normal. The breasts were small and had enlarged milk ducts.

Grünbaum¹¹ cites two cases of hysterectomy with ovariectomy in women of child-bearing age, one being a multipara. These women had secretions of milk following the operation for from eleven to seventeen days. He reviewed twenty-one cases of similar nature.

Dassier¹² noticed in climacteric women, secretion of milk following mastitis.

These cases lead to the very interesting question of the activity of the breast due to pathologic conditions. Tumors of the breast may be left out of consideration. We are here merely concerned with affections of the genital sphere.

Gellhorn has observed in the University Clinic, Bern, fourteen cases of mammary secretion in sterile women who exhibited uterine fibroids. He also found colostrum in the mammae in twenty-five out of forty-four cases of fibroids. He believes that the alteration of the blood by the uterine tumor causes the mammary symptoms. Irritation of the uterus by a strong galvanic current failed in his hands to cause milk secretion. He excludes reflex through the nervous system.

None of these authors endeavor to explain why the uterus is thus affected.

Sinclair⁸ offers this explanation: During pregnancy, the breasts are undergoing a change to prepare them for the purpose of lactation. Immediately after

delivery, there is an acceleration of this process, which is generally completed in from three to four days. Stimulation of the breasts by nursing at this time exerts a powerful influence in causing contraction of the uterus. Then, if lactation is gradually stopped, reevolution of the sexual functions becomes gradually complete; but if lactation has been carried to excess, it is natural to expect that it has exerted a greater than normal influence on the sexual organs. And when lactation is suddenly stopped, it is reasonable to suppose that the final stage of evolution will be more rapid than usual and attended by some unusual phenomenon. But this does not explain why the uterus suffers in prolonged lactation. Besides the uterus, other organs are affected.

Microscopic researches have shown that in all forms of true secretion, the active agents are cells which have the power of selecting from the blood the requisite materials; these cells, developed in the interior of the organ, become distended, burst or liquefy, and yield their contents to the excretory ducts.

In the mammary glands, as in other glandular structures, according to Goodsir,¹³ the inner surfaces of the ultimate milk follicles are covered by a layer of epithelial cells, the true agent in the process of secretion. As soon as one set of cells has emptied its contents, the cells die and are replaced by a new set of cells from the nuclei of the germinal cells of the follicles.

Bird¹³ obtained evidence that this alteration commences in the blood, and goes on during pregnancy as a preparation for lactation. The evidence is through the presence of kystein (which is nearly related to casein) in the urine during pregnancy, indicating the conversion of albumin into casein of the blood, and preventing its accumulation in this fluid before it is secreted by the mammae by this curious substance in the urine.

If these results are true, it does not seem so very strange that the secretion of milk cells should be permanent, under favorable circumstances, which cannot at present be specified, any more than that the secretion of the urine or bile, once commenced, should be permanent. The secretion of milk, abnormally continuous in the foregoing case, may be only a transfer of the office of freeing the system of nitrogen by the usual agents, the kidneys, to the unusual one, the mammae, which remove it by casein instead of by urea, from idiosyncrasy, the former being permanently formed in the blood.

Channing¹³ reports two cases of prolonged lactation lasting four and eight years; but the secretion of urine was not studied in them.

Coale¹³ deemed the analysis of the urine desirable and important, in such cases.

NEW-BORN

Billroth¹⁴ states that in a tolerably large number of cases of such tumors, he has never witnessed a coincidence with abnormal milk secretion. The occasional occurrence of milk secretion of the new-born of either sex is sufficiently known, but satisfactory explanation has not yet been given.

Steifensand¹⁵ was the first to call attention to the fact that, in the new-born, all glands exhibit pronounced activity.

Basch¹⁶ ascribes the phenomena to the welling up of the secretion to the surface, thereby loosening the hornified epithelium which clogs the orifices of the milk ducts.

Bumm¹⁷ says that the skin of the new-born is very sensitive and responds to the influence of air and light by reddening and exfoliation of the uppermost layers of the epidermis. This irritation is also the cause of the mammary secretion.

Longridge¹⁸ finds that in large children with an abundance of subcutaneous fat, the breasts are normally well developed irrespective of sex, and on pressure often secrete a fluid indistinguishable from milk.

Starling¹⁹ and Lane-Clayton state that there is a chemical factor in the body of the fetus, analogous to the one acting on the mother's breasts.

Halbau²⁰ concludes from his researches that pregnancy produces local phenomena in the fetus, which are identical with, though not so intense as, those in the organism of the mother. In a later study he attributes the causation of this mammary hypertrophy to an internal secretion of the placenta. He is of the opinion that the etiology of mammary secretion has nothing to do with the fetus, but is due to the internal secretion of the ovary; in pregnancy the function of the ovary is temporarily assumed by the placenta. In exceptional instances, lacteal secretion takes the place of menstruation.

CAUSE OF EYE AND BRAIN DISORDERS

Some report resultant eye and brain disorders. McKenzie⁸ was the first British writer to call attention to the effect of prolonged lactation on diseases of the eye. He described a case of retinitis due to this cause. It is usually bilateral.

Taylor⁸ stated that the injury may extend from a slight impairment of vision to a total loss of sight.

The brain is also seriously affected, and epilepsy is known to have developed. Luke⁸ mentions two cases of insanity as a result. Similar cases are also cited by Hewitt and Ashwell.⁸ Morton²¹ reports twenty-two cases showing inflammation of the brain and its membranes occurring in children in consequence of prolonged lactation.

Duval²² speaks of nonpuerperal mammary secretion and gives as causes: (1) menstruation; (2) tumors of the breasts; (3) affections of the utero-ovarian apparatus; (4) mechanical or psychic stimuli independent of any material modification of the organ, and (5) cases occurring after the menopause.

Spark²³ reports a serious case of galactorrhea with emaciation, anorexia, disturbed digestion, etc. It took four months to stop it. Abscesses had occurred in two successive confinements. Previous to the third confinement, extract of belladonna and glycerin were applied to the breasts every third night for a week. Milk appeared slightly for a day or two at the end of the week, and then discontinued.

Jacobius²⁴ was able to revive nursing in from three to twenty-six days after it was discontinued, by using

a rubber nipple attached to a rubber tube, which the mother sucked. This was effective treatment with many patients that never nursed a child, not even during the puerperium.

CASES OF PROLONGED LACTATION

Mention will be made of some interesting cases:

Mrs. E. B., aged 31, born in Chicago, with unimportant family history, gave birth to a child eleven years ago, and had an extra-uterine pregnancy of five and one-half months' duration, three years ago. Both breasts have secreted rich, creamy milk since the birth of the child eleven years ago. (For complete report, with unique surgical complications of this case, see: Seifert, M. J.: *Ectopic Gestation, Internat. Clin. Series* 30, 2, 1920.)

Arnheim²⁵ reported a case of a woman of twenty-six who had been confined four years before, and since then had had a profuse mammary secretion that resisted all known methods of treatment.

Kneeland¹³ reported a case in a woman of 35, who gave birth to a child five years before. She nursed it until it was 2 years old, when it died of chronic hydrocephalus. Her husband died when the child was 2 years old. Milk secretion was very profuse, and although not pregnant again, she secreted milk in abundance five years after the birth of the child.

Walsh⁸ reported a case in a colored woman of 23; her first child was 5½ years old, whom she had nursed for two years. Her breasts had not been dry since, and she had been accustomed to milk herself two or three times daily. Three years before, she had an abscess of the breast, and a year later, miscarriage followed by dysmenorrhea. Her breasts were large and filled with milk, which could be expressed on the slightest pressure. Belladonna, turpentine and strapping were tried, but milk continued to secrete in spite of treatment.

Nikolski²⁶ reports a case of a woman of 31, delivered of a child five years before, who lived but a short time. She continued to secrete milk to date.

Edelberg²⁷ reports a case in a widow of 27 who married at 18, and had never menstruated. She had irregular menstruation after marriage. Four years later she became pregnant, menstruation ceased, and she was later delivered of a healthy child. There was no menstruation for eleven months, whereupon it again became irregular. No further pregnancy occurred, but there was copious secretion of milk six years after the birth of the child. The patient lacked in sex sense. No gynecologic examination could be obtained.

Clarke²⁸ reports a case of a mother who nursed her child for five years and two months. She menstruated only twice during this period. On a physician's advice the child was weaned, and the milk secretion soon stopped.

Cheinisse²⁹ cites a case of latent lactation, with anemia and debility, two years after the weaning of the child. Milk was secreted, but expressed only on pressure.

Beltz³⁰ reports a case of latent lactation four years after the child was weaned. The secretion increased at menstrual periods, but was obtained only on pressure.

Dr. Ellittson cites a case of a woman who secreted milk after miscarriage at seven months; then, another, who had never been pregnant. He also cites a case of a young woman who suffered from dysmenorrhea as a result of ovarian trouble. She had never been pregnant, but had mammary secretion of milk.

EXTRAORDINARILY PROLONGED CASES

There are several cases on record of extraordinarily prolonged lactation.

Kamneff³¹ reports a case of thirty-two years' duration. Cazeaux¹ describes the case of a woman in whom an abundance of milk was secreted for forty-seven years.

Siegarth³² quotes cases of five grandmothers who had borne from nine to seventeen children of their own and nursed each one for two years, as well as suckled their grandchildren—one of these for more than twenty-two years, and twelve of the children for 280 months. In spite of unfavorable social and economic conditions, there was not a case of rickets among them, and only one of these children died in early infancy.

Landau³³ quotes Billroth regarding a woman, aged 82, whose breasts were functioning. The same author removed the ovaries in a woman, aged 29, who later on developed milk in her breasts without pregnancy. He also cites a case of a woman, aged 24, whose milk in one breast was sweet, and in the other salty. The child refused nursing. Chemical analysis was not obtained.

VIRGINS

The occurrence of copious lacteal secretion in the virgin was noticed and discussed by the illustrious father of medicine. His observations have since been periodically added to by records of new cases, in all ages down to our own.

The American physiologist Dunglison emphasized the fact that very active and copious lactation may be present without previous impregnation, "for it has been witnessed in the unquestionable virgin, in the superannuated female, and even in the male sex."

Knott³⁴ cites three cases of nurse girls who were entrusted with the care of infants for the night. In order to quiet the babies, they allowed them to play with their breasts and suckle their nipples. Increased sense of fullness and warmth was followed in a few days by copious secretion of milk. It promptly yielded to simple treatment of belladonna externally and internally. Another case of a girl of 8 who suckled her infant brother for a month was recorded by the French obstetrician Baudelocque.

LeRoy³⁵ mentions an African Jewess, with a history of marked nervousness in the family, but no stigmas, who menstruated at 10 and developed secretion of milk in considerable quantity. At 23 she developed symptoms of mania and was placed in an institution in Paris. The breasts were well developed, but the nipples absent, so that in this case the secretion could not be attributed to a stimulation, from the suction of nipples. There was extreme erotism in her talk, and she was proud of her anomalous function.

Noel³⁶ mentions the case of a young married woman who had never had sexual intercourse. She was called

36. Noel: *Echo méd. de Cévennes*, 1901, p. 207.

on to care for an infant 6 months old. To quiet it, she took it to her breasts, and secretion soon followed.

Blum³⁷ reports the case of a girl, aged 17, with two developed mammae in their normal places, who had in the region of the mons veneris a third mamma, the size of a goose egg, with seven nipples. Four of these secreted regularly a copious amount of colostrum before and during the first day of menstruation. The two normal mammae did not secrete at all.

VIRGIN ANIMALS

These references are also corroborated by animal breeders. Virgin sheep, dogs and rabbits have occasionally been found to secrete milk.

Harvey³⁸ states that overfed female dogs which admit the dog without fecundation following steal away the whelps of another female dog, tend and lick them, and fight fiercely for them. Others have milk and colostrum in their teats, and are subject to diseases of those that have whelped.

Noel³⁶ cites the case of an ape confined in a cage, an unquestionable virgo intactu, which developed secretion of milk in her teats by occasionally rubbing them. It lasted nine months, and reappeared at intervals. This author also cites several instances in which women were able to nurse after an interval of four months.

PHANTOM PREGNANCIES AND VICARIOUS MENSTRUATION

Gellhorn³ cites several cases of phantom pregnancy with mammary secretions. These were due, either to the desire or the fear of pregnancy, and in one case to the sight of milk secretion.

Pusch and Courty³⁹ collected twenty-six instances in which there was vicarious menstruation.

Landau³³ and Gautier⁴⁰ report a similar case; the latter, that of a virgin.

SUPERANNUATED FEMALES

Turning our attention to the superannuated female, Dr. Gordon Smith refers to a manuscript by Sir Hans Sloane containing the record of a woman of 68 who had borne a child more than twenty years before, and who had nursed all her grandchildren, one after the other.

Professor Hall of the University of Maryland reports the case of a widow, aged 50, whom he had witnessed nursing her grandchildren, although she had not borne a child of her own for twenty years. In this case the child was put to the breast to quiet it, in the process of weaning.

Dr. Francis of New York narrated a case of a woman who for fourteen years after the birth of her child secreted milk in great abundance.

Dr. Kennedy of Ashby de la Zouch has described the case of a woman who menstruated during lactation, suckled children through the full course of forty-seven years, and in her eighty-first year had a moderate but regular supply of milk, rich and sweet, and not differing from that secreted by young, healthy mothers.

Stack⁴¹ tells of a woman of 64 who had not borne a child in sixteen years, but nursed her grandchildren, one after the other.

LACTATION IN THE MALE

Finally, I will mention the still more anomalous phenomenon of lactation in the male.

Knott³⁴ tells of Professor Hall exhibiting to his obstetric class in 1827 a colored man, aged 55, who had large, soft, well formed mammae, rather more conical than those of a female, and projecting fully 7 inches from the chest, with perfect and large nipples. The glandular structure was in every respect like that of a female. This man officiated as wet nurse for his mistress, and when the milk was no longer required, great difficulty was experienced in arresting the secretion. His genital organs were fully developed.

There has been cited⁴² the case of a man about 70, who was left a widower with an infant, aged 2 months. He took the baby to his breast and soon secreted enough milk to rear him. His breasts were large—larger than those of some women.

Knott⁴³ cites the case of a Chippewa Indian, who also was left a widower with a young infant. He cared for him as a mother would, his breasts began to secrete milk, and he raised the child.

Dorland states that it is not at all uncommon among the men of the lower classes of Siam to nurse the babies, either altogether or alternately with the mothers.

Cases of male domestic animals have been cited⁴² whose breasts secrete milk in abundance.

SUMMARY AND CONCLUSION

We have seen, in the foregoing, that lacteal secretion not only occurs during pregnancy and the puerperium, but also may appear in the new-born, in the growing child, in the adult virgin, in the old woman, and in the male.

It may be prolonged indefinitely after childbirth, and may be associated with certain pathologic conditions in the genital sphere, as well as after hysterectomy and ovariectomy.

Aside from the intense scientific interest in the etiology of lacteal secretion, which is still obscure, there is also considerable practical importance attached to abnormal activity of the mammary glands, and a thorough knowledge of the atypical functions of these organs is indispensable to the expert in medicolegal practice.

The inference is: Most mothers could nurse their babies if, instead of shirking, heeding false advice, or taking galactagogues, they would stimulate their breasts by normal methods.

30 North Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. WILLIAM KOHLMANN, New Orleans: Dr. Seifert has collected all the literature and at the same time brings out some points on the practical facts of lactation. He has shown that the secretion of milk takes place not only during pregnancy, but under other conditions. We have all seen a woman who either wishes or is afraid to be pregnant and yet secretes colostrum, if not milk. During inflammatory conditions of the uterus, milk secretion may not be very frequent. I operated on a woman five years ago following infection of childbirth. She had to be operated on again last fall because of infection. Immediately after recovery she was secreting milk and did so for about two weeks. From the medicolegal aspect this is important. It could be brought up that a woman was pregnant because of the presence of

milk in her breast. I wish to emphasize two points: first, the hypersecretion of milk, and, second, protective secretion of milk. Hypersecretion of milk is to be spoken of if the secretion exceeds two pints a day. Ordinarily, a woman secretes half a pint a day. Of course, there are women who secrete a great deal of milk and can nurse several babies, especially twins. Unfortunately, many women who have a chronic disease, like tuberculosis, are inclined to secrete a great deal of milk. To let her continue to secrete milk without attempt to stop it would interfere with the health of the woman, and milk of that kind is no doubt unhealthy and may be followed by complications of the digestive organs of the child. There seems to be a decrease of mothers who are able to nurse their children. Unfortunately, there is little we can do to stimulate the secretion. The only thing we can do is to regulate the general health and to try to increase the secretion of milk. We should try to increase the flow of milk because the child will do much better when nursed by the mother than to be fed by artificial means.

PROLAPSE OF THE FEMALE URETHRA*

RICHARD R. SMITH, M.D.

GRAND RAPIDS, MICH.

My object in presenting this paper is to call attention to the condition designated by its title, to describe it and to offer a simple means for its correction. I hardly need say that so-called bladder symptoms are among the most annoying of all the discomforts that

Fig. 1.—Diagram of operation on meatus itself. This is done for the purpose of narrowing a dilated orifice and restoring normal protection to the urethral mucous membrane.

arise from childbirth injuries. We have recognized that they are due directly, though perhaps not entirely, to the loss of integrity of structures anterior to the vagina which have intimately to do with the support of the bladder and the urethra. In general these injuries are more important than the prolapse of the posterior wall and rectocele which follow the separation or tearing of the levators. But far more consideration has been given to the perineum and its repair than to the defects in these anterior structures. It would be difficult to understand why the condition to be described has not received earlier attention, and even today is so commonly overlooked, if we did not realize that cystocele and its associated lesions have only recently received the attention they deserve.

When a woman comes to us complaining of frequent and perhaps painful urination, together with more or less constant discomfort in the region of the bladder, or of other symptoms associated with the act of micturition, we systematically examine the bladder and upper urinary passages for a cause of the trouble, which we think of largely in terms of infection. At the same time we look for mechanical defects. If we find a cystocele we are likely to consider this the extent of the mechanical trouble and offer its surgical correction as a means of relief.

In making such an examination we note and consider the extent of the cystocele, the position and condition of the uterus, and the integrity of the perineum and posterior vaginal wall. We are likely, however, not to inspect thoroughly and examine the meatus urinarius. With the patient on her back and relaxed,

Fig. 2.—Denudation and suturing of anterior vaginal wall above meatus. After obtaining a good hold on the forward edge of the mucous membrane, a rather deep bite is taken into the firm tissue beneath the pubic bone, care being taken, of course, to avoid the urethra. When tied, the meatus is drawn upward and its normal protected position restored.

the meatus and anterior vaginal wall close to it protrude but little, if any, whatever the condition present, and are likely to be regarded as quite normal. Ask the woman to strain, however, and if there has been an injury at this point the meatus and the anterior vaginal wall back of it bulge forward and roll upward, bringing them into marked prominence.

Close observation will not infrequently disclose an edema of these structures. Most important is the condition of the meatus itself. The mucosa at the lower end of the urethra is seen to roll slightly out of the meatus, exposing to view a bit of the tender lining of the canal. The meatus may be found to be larger than usual, its two small lips torn or stretched and offering a very imperfect covering for the sensitive membrane within. The mucosa is not infrequently the seat of a so-called caruncle, which is sometimes exquisitely sensitive, though frequently very little so.

Imagine, now, the patient up and about, or straining to evacuate the bowel or bladder. We must, of course, have the protrusion produced many times a day. Ask the patient whether there is tenderness at this point and whether she has discomfort there. The answer will frequently be "yes." She will tell you that her clothing often irritates her and that bathing the parts or any roughness produces the same results. It occasionally happens that close questioning will reveal the fact that practically all her symptoms are those just mentioned. At other times they are but a part, though an important part, of the urinary symptoms of which she complains. Frequent urination has many causes. The usual ones lie perhaps in the urinary passages above the meatus,

Fig. 3.—Lines of incision used when other operations are performed requiring the usual longitudinal incision in the anterior vaginal wall.

* Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

but I have occasionally seen it produced by this condition alone. It is well to question, when painful urination is complained of, as to its nature. The passage of urine over a swollen, irritated meatus produces burning and discomfort at this point.

In considering the correction of cystocele, with or without a prolapse of the uterus, I would urge that the condition of the urethra be observed, and if it is prolapsed, that this condition be corrected at the same time, or, if the latter condition alone exists, that the slight operation necessary to its correction be offered the patient. The operation will vary somewhat according to the circumstances. Let us assume first that the prolapse of the urethra exists alone. First we will remove the caruncle or protruding mucosa. This should be done with greatest delicacy, because the tissue is extremely soft and bleeds freely. A very fine stitch or two on a fine needle is occasionally, but not always, necessary. More important is the closure of the meatus to its normal dimensions, and this is done by making a small denudation (Fig. 1), removing a bit of the circumference of the meatus and denuding a little of the surface beneath it as in the diagram. The placing of the fine chromicized sutures will vary according to the individual case, but there is little difficulty in this part of the operation. There follows a large triangular denudation of the anterior vaginal wall that protrudes (Fig. 2), the base of which is placed as high as the under edge of the pubic bone, or slightly higher, so that when it is closed by sutures the meatus is drawn back to a normal position. The stitches, which must, of course, avoid the urethra, are inserted deep enough to obtain a good hold of the firm tissue close to the pubic bone. I commonly employ chromicized catgut.

If an ordinary cystocele operation is performed, the usual median incision along the anterior vaginal wall should continue well forward, and should then be broken by a transverse one, which forms the base of the triangle described above, the operation being completed in the same way (Fig. 3). When an interposition operation is performed, I would urge bringing the fundus close to the pubis and stitching it rather firmly there, the retaining stitch being placed directly on top of the fundus. This, I believe, will prevent a protrusion afterward of the anterior wall at this point and, if combined with a correction of a previously existing protrusion of the meatus and anterior wall, will do away with and prevent the occurrence of this disagreeable result; at least, I have had no trouble since I have been more particular about doing it this way.

I am aware that many gynecologists have recognized the condition that is the subject of this paper and have adopted similar means of correcting it. I am sure, however, that the practice has not been universally followed and has not been sufficiently emphasized.

ABSTRACT OF DISCUSSION

DR. S. M. D. CLARK, New Orleans: Murette's article shed new light on the true pathology of this incontinence of urine. The walls of the urethra are parallel normally. In childbirth the structures that support the posterior vaginal wall are damaged in such a way as to cause a prolapse, a sagging, and instead of having parallel urethral walls a bottle formation results. That is the basis of the whole trouble. By reestablishing the parallelism of the urethral walls, which Dr. Smith's procedure does in the large majority of cases, the incontinence is overcome. Murette's procedure, which we have adopted in our clinic, does that very effectually.

DR. F. F. LAWRENCE, Columbus, Ohio: Before a prolapse of the urethra can occur, as described by the essayist, there must be a descent of the uterus, together with the formation of the cystocele. A cystocele or urethral prolapse cannot develop so long as the uterus lies in its normal axis. The first thing that must occur is the dropping downward and forward of the cervix, thus relaxing and permitting pouching of the anterior vaginal wall with the development of cystocele. Any operation which shortens the anterior vaginal wall tends to draw the cervix forward, and must fail in its object because it favors the descent of the uterus. I very much doubt if any of us have ever seen a cystocele when the patient had a good perineum to support and hold the cervix in its proper position. Hence, the first and most important thing to do is to rebuild the perineum, and this must be done in a manner to get a wide infolding of the deep pelvic fascia and perineal muscles at its upper point, so as to hold the cervix back in its normal position. Then with the anterior colporrhaphy performed in such manner that the suture line is in the long axis of the vagina, we will get results. Any operation which produces a crosswise cicatrix will shorten the vagina, tending to pull the cervix forward and widen it, favoring the development of cystocele.

DR. ARTHUR H. CURTIS, Chicago: A great number of patients complain of symptoms and on routine examination we fail to recognize the pathology. It is necessary in such instances to examine the patient in the standing position. In the recumbent posture, even when the patient strains, we will often overlook a relaxed urethra and cystocele and even a prolapse of the uterus. When the patient is standing these lesions are almost invariably evident and easily diagnosed. As to urethral caruncle: the more common form is that in which there is a moderate prolapse of the urethra with the development of redundant granulations on this prolapsed tissue. About one year and a half ago I noted that there was usually a cystocele in conjunction with the caruncle. Since then I have failed to observe a single caruncle in which there was not a urethrocele or cystocele. I have since performed all caruncle operations with removal of the caruncle, combined with slight reparative operations on the prolapsed urethra and cystocele. In none of these instances have I seen a recurrence. Therefore, I believe it would be a good plan in cases where we find a caruncle to look carefully for the causative urethrocele or cystocele.

DR. RICHARD R. SMITH, Grand Rapids, Mich.: I did not mention incontinence as one of the symptoms for which this operation should be done, nor did I mention cystocele, with which this prolapse of the urethra is so often associated. That is a subject quite in itself. This operation is not intended to correct the cystocele. The standing of the patient during examination is a very important point. Snipping off the caruncle almost invariably leads to recurrence. It is necessary to protect the mucous membrane at the lower end of the urethra.

What Is Diabetes?—All our present knowledge and particularly the recent experimental work of Allen show that the underlying deficiency is a failure of the internal secretion of the pancreas, with consequent inability to convert sugar from the crystalline to the colloid form, in which form it must be present before it can be utilized by the body cell. Such failure on the part of the internal secretion of the pancreas may or may not be related to gross disease; it seems reasonably certain that nervous disturbance may disturb the equilibrium normally maintained between the organs of the endocrine system, and undoubtedly nervous disorder frequently upsets the balance of a diabetic. There is reason to believe that the white races generally are overtaxing the pancreatic function; the present day enormous consumption of carbohydrate, and particularly of sugar, is a new thing for the race. In America the consumption of sugar per head has risen from 4,990 grams per head in 1810 to 40,700 grams per head in 1916; perhaps a sugar famine would not be an unmixed evil.—J. F. Wilkinson, *Med. J. Australia*, Feb. 14, 1920.

TYPHOID REDUCTION IN SOUTH
CAROLINACOMPARATIVE RESULTS IN COUNTIES WITH AND
WITHOUT HEALTH ORGANIZATIONS *

L. A. RISER, M.D.

Director, County Health Work, South Carolina State Board of Health
COLUMBIA, S. C.

The vital statistics department was organized in South Carolina in 1915, and we have no accurate records of deaths from typhoid previous to that year. In this paper I will attempt to show how typhoid fever has decreased, and what methods are being used to effect this decrease. The decrease has been gradual

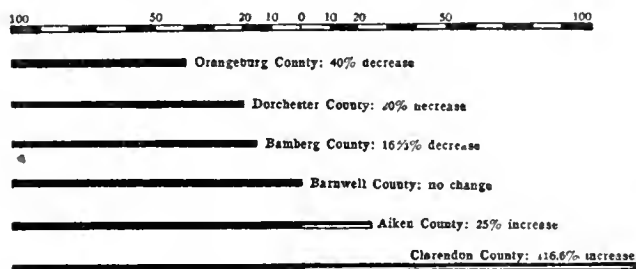

Fig. 1.—Increase and decrease in incidence of typhoid, 1917-1919: Orangeburg has had a county health department for three years. It has an area of 960 square miles and has made the same appropriations each year as Darlington with 600 square miles. Other counties compared have had no city or county health organizations.

since 1915, with the exception of 1918, during which year the army camps brought more than a hundred thousand people to the state. This does not refer to soldiers, but to workmen and camp followers who were not under army restrictions, and we credit to this fact the increase in 1918, as the cities in which these camps were constructed showed very large increases, some of them doubling their number of deaths of the preceding year.

ORGANIZATION

In 1917 the first county health unit was formed in South Carolina. This organization was perfected in Orangeburg County, one of the largest and most prosperous counties in the state. The unit consisted of a physician as director, with a corps of inspectors and carpenters. Greenwood County also took up the work during the year.

TYPE OF WORK

The ultimate object of the health unit was to stamp out typhoid fever and other intestinal diseases. The type of work was both educational and constructive. The physician gave lantern slide lectures in each school district on various health subjects, but stressed intestinal diseases spread by bad sanitation. The inspectors made a survey of the district, visiting each home and securing data as to living conditions of the family and sanitary surroundings of the home. Wherever possible the inspector persuaded the householder to put in a sanitary privy; if the inspector failed, then the physician made a personal visit to the home. The carpenters assisted in the construction of the privies. Specimens of feces were collected and examined for intestinal parasites, and when the

patients were found infected they were given free treatment. By circulars, posters, personal letters, exhibits, school contests, public lectures, newspaper publicity and personal interviews the importance of sanitation was constantly kept before the public

GROWTH AND PROGRESS OF COUNTY
ORGANIZATIONS

In 1918 four full-time county health organizations were perfected, in 1919 six and in 1920 seven. In 1918 medical inspection of rural schools was made a part of the work, and public health nurses were added to the county units. Darlington County is probably the only county in the South in which every rural schoolchild, white or colored, has received a medical examination and a follow-up visit from a nurse.

Each organization is now designated as a county health department, and the physician has by legislation been made the county health officer, and his duties are prescribed. Counties which in 1917 appropriated \$2,000 for this work are now appropriating \$5,000, and in addition cars are furnished the nurses by local organizations. Our state appropriation for 1917 was \$7,000 for county health work; for 1920 we have been given \$27,000, a portion of which will be used for a traveling moving picture unit.

DIFFICULTIES ENCOUNTERED

In 1917 comparatively few sanitary privies were built—pioneer work is always difficult. The war with all its effects, the shortage of labor and material, the physical unrest, the breaking up of departments by the volunteering of men (every county director but one, as well as the state director, having volunteered and entered service) crippled the work for a time. The present high prices and low salaries are keeping up the difficulties, but with it all we have something to show for our work.

RESULTS OF WORK

Each county in which we have worked two years has shown a decided decrease in typhoid; the first year an increase is usually shown, owing, perhaps, to better reporting. We have selected this disease as a type of intestinal disease and have selected Darlington and

Fig. 2.—Increase and decrease in incidence of typhoid, 1917-1919: Darlington has had a county health department two years. Florence has had a city but no county health department. Chesterfield and Marlboro have had neither city nor county health departments.

Orangeburg counties for comparative results with surrounding counties having no health organizations, as these counties have had no campaigns of giving free typhoid inoculations. We are giving results from each county touching Darlington where no work has been done, and each touching Orangeburg where no work has been done, with the exception of two black counties. These two counties with a large black population give poor reports, as so many of the negroes are unattended by physicians and "fever" is given as a cause of death. Mr. C. W. Miller, our vital statistician, who helped me to get up these statistics, thought the statistics of these two counties unreliable.

* Read before the Section on Preventive Medicine and Public Health at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

It will be noticed (Chart 2) that each county touching and compared with Darlington shows an increase, while Darlington shows a decrease in typhoid—Darlington shows a decrease of 57.9 per cent. from 1917 to 1919.

Orangeburg shows a decrease of 40 per cent. (Chart 1). This is one of the largest and most populous counties in South Carolina, and it would naturally take longer for results to show. The state at large has gradually decreased its typhoid death rate, as illustrated in Chart 3, from 35.2 per hundred thousand in 1915 to 21.7 per hundred thousand in 1919.

CONCLUSIONS

The reduction of typhoid fever is largely a matter of education. The building of privies alone will not check typhoid entirely, but will reduce it. We have purposely held no campaigns of free inoculations of antityphoid serum in Darlington and Orangeburg counties, and the results shown are due to educational work and privy building alone, and not to inoculations. If this disease can be so materially reduced by education, it would seem that all other diseases of which the cause is known could be reduced in a similar way.

A county health organization is necessary, as one physician or nurse without assistance is not adequate for the supervision of the health conditions of a whole county.

ABSTRACT OF DISCUSSION

DR. W. S. LEATHERS, Jackson, Miss.: In Mississippi we have organizations at work in different counties, and the results we have obtained are along the same lines which have been indicated by Dr. Riser. In one county in the state we had about 230 typhoid cases a year. This county was leading the state in typhoid. In that county we organized one of these units and conducted what we termed an intensive health campaign. We built about 2,000 privies, visited every home in the county, obtained the name of every man, woman and child we could find and tried in every possible way to get in touch with the people, and to determine the conditions which existed in the county. We instituted measures which we thought were necessary for the prevention of intestinal diseases. This intensive campaign was conducted in 1917. In 1918 there were fifty cases of typhoid and eight deaths. That is an example of what may be accomplished in every county in every state in the South; in fact, that may be done wherever typhoid exists. In 1914 there were approximately 6,066 cases of typhoid in the state. In 1919 there were 3,660 cases of typhoid. We have been able to get 90 per cent. of the doctors of the state to report their morbidity statistics for a period of six years. We assume that there are errors in these reports, but the errors are uniform, in all probability, for the same doctors have been making the reports. The decrease in figures is unmistakably very significant, and we can draw from these figures a very definite conclusion so far as reduction of typhoid fever is concerned. The education of the people is basic. One of the most effective measures is personal demonstration. We ought to go into the various communities and work with the people, and show them by

practical demonstration what to do. We can demonstrate in a community how to build a privy and get people to build privies by demonstration methods, and illustrate that by such methods we will get very definite results in the reduction of typhoid fever. The time is rapidly approaching when typhoid fever will be a relatively rare disease.

DR. JOHN D. McLEAN, Philadelphia: It has been stated that the incidence of typhoid fever indicates the health of a state or of a community. If that be so, the report we received in Pennsylvania last week, would indicate that Pennsylvania is becoming a very healthy state indeed. We have found that the greatest number of epidemics have been caused by carrying the disease from one person to other persons through the water and through the milk. If that be true, then the lessening of typhoid fever must be effected through supplying pure drinking water and pure milk. Pennsylvania, therefore, has determined, as far as it possibly can be done, to control the water supply of the state. We have also determined that the people shall drink good milk, clean milk. To bring this about we have, with other measures, drawn two model health ordinances. One provides how an organized community can get pure water to drink, and the other provides how this community can get pure milk to drink. We ask those responsible for the laws and for the expenditure of the finances in these communities to pass these ordinances. We hope to secure pure water and pure milk. Educate the public to the need for these things so that they will tell those responsible for the expenditure of their money that they must install a filter plant or they must install a pasteurizing plant for milk.

How is that done? Choose from among the existing agencies one, the Red Cross, the Emergency Aid, the Y. M. C. A., the Y. W. C. A., whatever it may be in that particular community, and create an advisory board to tell the councillors that they represent public opinion, and ask them to spend the money. In Pennsylvania we investigate every case of typhoid and take measures to prevent a spread of the disease and in that way we have lessened the number of cases.

DR. G. C. CHANDLER, Shreveport, La.: The sources of these diseases are the excretions of human beings, and in getting rid of these excretions and the germs they contain you will have a healthy city and save many lives. One of the best means of suppressing typhoid fever is to take milk samples, and wherever you find water in the milk, fine the milkman the limit. By doing that you will stop the spread of typhoid fever from milk. Typhoid fever can be stamped out easily if you know the source of the disease. Shreveport, up to 1918, used filtered bayou water for its water supply. In 1911, when they had about the lowest number of deaths from typhoid fever, there were 104 deaths among the residents of Shreveport from fevers, diarrhea and dysentery. There were only about 25,000 people there then, and that was about the lowest death rate we had.

DR. JOHN A. FERRELL, New York City: The public health work in South Carolina is a demonstration which carries conviction to the people and to their legislative representatives. There is uniformity of opinion that to succeed in public health work we must first educate the public. There is some difference of opinion as to the best method for conducting the educational program. The opinion is held by some enthusiasts that if you lecture to the people and distribute literature among them they will readily accept what you have to say, do what you tell them to do, and vote the money required for the work. To these enthusiasts the control of disease is a very simple undertaking. Once you have the knowledge as to the cause of the disease and its mode of spread, all you have to do is to tell the people about it, these optimists believe, and the job is done. Health officers of extended experience have learned that the people can be interested in control measures, that they are open minded, but that they have had unsound advice on many occasions. They are ready to be shown in terms that are simple and understandable, and when convinced that the proposed program has merit from a business standpoint and will yield a satisfactory return on the investment you may depend on them to give support to their leaders in public health. This method of developing public health work has been followed in a number of states, particu-

Fig. 3.—Death rate per hundred thousand.

larly in the South. South Carolina, for example, in the year 1908 had less than \$10,000 state appropriation for health work. The appropriation voted by the legislature which recently adjourned approximates \$155,000 a year, exclusive of the appropriation for tuberculosis work. The growth in a number of other southern states has likewise been phenomenal. Dr. Riser recently reported that the South Carolina legislature actually appropriated more money for the health program than was requested by the executive officers of the state board of health. That the people in these states have been convinced that public health work is worth while is evidenced by the growth in the state appropriations for eleven southern states from about a quarter of a million dollars in 1910 to more than two million dollars at present. Ten years ago a full time health officer in these states was the exception. Now, they are numerous and, in the near future, I believe, will be the rule. The state's funds are being generously supplemented by towns and counties for the purpose of establishing local departments of health work in cooperation with the state board of health. These developments should be a source of keen gratification to the public health officers who have had the wisdom and ability to give the people a large value for their investments in public health.

DR. LUTHER A. RISER, Columbia, S. C.: The figures I gave here are not figures of typhoid fever cases, but of typhoid fever deaths. Dr. Leathers spoke of the necessity for demonstrations. I consider demonstrations as part of this educational work; it is all educational, but the demonstration is just a type of the educational work. Dr. Chandler spoke of the reduction of typhoid fever as being an indication of the reduction of other diseases of that type. It is also an indication of the reduction of all types of diseases, because in these counties you will find a reduction of tuberculosis just as well as you will of typhoid fever and intestinal diseases, and the death rate has also decreased in those counties more than it has in those counties where no educational work of this type has been done.

THE TRAINING OF INDUSTRIAL PHYSICIANS*

J. A. WATKINS, A.B., M.D.

Director, Industrial Medicine Division, Department of Industrial Medicine and Public Health, University of Cincinnati College of Medicine; Medical Director, Lunkenheimer Company

CINCINNATI

It took the medical profession quite a while to realize that the possession of a sound medical education did not, per se, qualify a man adequately to carry on the duties of a health officer. The profession has likewise been somewhat slow to recognize that the acquisition of sound surgical technic or skilled diagnostic ability does not qualify a man to carry on the duties of an industrial physician. Just as public health work led to the requirement of specialized training, so with the development of industrial medicine has come the realization that herein lies a specialty in medical science that requires of the physician special theoretical and practical training, which has in the past ordinarily been outside the sphere of medical education. Moreover, it is just becoming apparent that the profession has in a measure failed to grasp an opportunity for the extension of its influence and the utilization of medical knowledge and experience toward the prevention of disability and the shortening of the disability period, the profession's duty to society.

The need for special training of physicians engaged in industrial work has been recognized by the profes-

sion none too soon nor too widely. Modern industrial management has been quick to distinguish between the physician trained in industrial medicine and the physician catering to industrial practice.

Urban health officers have long seen in the work of the industrial physician valuable and much needed assistance in constructive health work, for such can be prosecuted intensively among industrial personnel as it can in no other group.

Civic bodies, social workers, large industrial corporations and community organizations have seen that the old-time plant physician did not render to industrial personnel the maximum service that could justly be expected of medical science.

With the realization by these several groups of society of the need for specialized training of medical men, several of our colleges have offered such training facilities.

PRESENT FACILITIES FOR TRAINING¹

There are thirty-one medical colleges or universities offering training facilities or instruction in industrial medicine or related subjects. Of these there are two schools offering courses in this subject, leading to certification on satisfactory completion; ten schools offer a limited amount of work in the curriculums leading to the degree of Doctor of Medicine; four universities offer some instruction in vocational hygiene during the course leading to one of four degrees in public health, the requirements of which are not standardized, while fifteen schools offering postgraduate public health instruction include limited instruction in industrial medicine or related subjects.

Thus we see that there are, first, inadequate opportunities in the United States for the physician to receive either theoretical or well directed, practical instruction in industrial medicine, and secondly, that such courses of instruction as are offered show a marked lack of uniformity in conduct and standardization both of requirements for entrance and completion (certification).

It is hoped that the profession will interest itself sufficiently in this exceedingly important function of medicine to stimulate a more general inauguration of industrial medical training facilities in our medical schools, with a standardization of requirements for completion and some uniformity in type of courses of instruction.

In anticipating such action on the part of our schools, it is essential that a clear and complete understanding as to the basic requirements of an industrial physician be fully discussed, toward the end that the necessary facilities for the training of such specialists be provided. It is a discussion of this subject that I have been asked to open.

On attaining the degree of Doctor of Medicine, the future industrial physician should look forward to assuredly one year, and preferably two years of postgraduate general medical experience before he assumes the study of industrial medicine. One year of this time, at least, should be spent in internship. The experience to be gained in outpatient clinics, in dispensary work, on emergency service and admitting wards in general hospitals will be found of value. Such postgraduate experience should be supplemented, if possible, by work in night clinics, industrial clinics, industrial health centers, public health agencies and

* Read before the Section on Preventive Medicine and Public Health at the Seventy-First Annual Session of the American Medical Association, New Orleans, April, 1920.

1. I am indebted to Mr. Royal Meeker of the Bureau of Labor Statistics for the information and data here given.

municipal dispensaries. It is in such places that he will study, if he is thoughtful, not only the sick individual, but the sick as a group. Such experience, supplemented by some general private practice, is invaluable. If not socially minded, he will acquire a social point of view, and he will see at first hand the medical, social and economic problems confronting society and awaiting the assistance that the medical profession has in its power to grant.

SPECIALIZED TRAINING

The completion of this instruction and experience, if taken advantage of, should afford a good groundwork for entering industrial medical training. This is post-graduate work. It should be given in an A-1 college, either in a special department or in a division of the department of preventive medicine.

HYGIENIC TRAINING

Hygienic instruction will fall naturally into two classes, medical and engineering.

The first should cover the subject of vocational hygiene in its entirety. The student should be taught to recognize occupational affections, not only direct, specific occupational diseases, but the indirect effect of occupation on the physiology of man, though masked by subsequent acute intercurrent pathologic conditions. Among these none is more important than that of industrial fatigue. In this subject the basic physiologic facts should be acquired, but he should not allow himself to become too academic, realizing that industry is essentially practical. The student of industrial medical science should here acquire a knowledge of personal hygiene in all its aspects and learn to impart this knowledge to industrial workers in a manner which is characterized essentially by clarity and brevity, so that large groups badly in need of benefits to be derived from this information can thus profit.

Foremost in personal hygiene is dental prophylaxis. Though this specialty in industrial medicine will be handled by the dental profession, yet it should not be introduced in industry without a medical department, and should be a part of such organization. The industrial physician should possess sufficient information on the subject to apply profitably the specialized knowledge of the oral hygienist or dentist.

The student at this time should acquire an extensive knowledge of medical supervisory systems. The experience and knowledge of those engaged in this type of work both in military organizations, public schools, insurance companies, industries and other organizations should be carefully acquired. He will at this time learn what is meant by, the purpose of, and the limitations of the physical examination in industry. The distinction between physical examination and medical inspection should be clear, with the scope and function of each definitely outlined. He should understand the inauguration and conduct of follow-up systems, and should profit by the knowledge and experience of those engaged in the organization and conduct of visiting nurse systems.

The industrial medical student can also profitably learn of those who have specialized in the subject of recreation and athletics for groups, and be prepared to institute such activities among industrial workers where indicated, in a manner which is consistent with the type of industry, the character of the work performed, and with other circumstances.

Engineering hygienic instruction is ordinarily outside the scope of training of the medical man. Many of these subjects are very broad and have given rise to specialists among engineers. The industrial physician, however, should have a sound knowledge of the subject, for on him will fall the duty of acquiring the desired conditions, even if he himself is not capable of carrying them out in detail. I refer to such as heating and ventilating systems and the problems of illumination, particularly artificial illumination. Elementary engineering principles of exhaust and supply systems should be well understood, and a thorough knowledge of the mechanical principles involved in the design, construction and operation of drinking water systems should be obtained. A study of the engineering phases of housing is of great value. He should acquire knowledge of the various sanitary equipment, such as toilet and wash-up facilities; baths, lockers; water supply and sewage disposal systems; and industrial waste disposal methods, also the specifications, outlay and conduct of restaurant or cafeteria systems; and he should be able to discuss with specialists in these various fields the basic problems presenting themselves, and so act as the adviser to the industrial management on these problems.

INDUSTRIAL CONSIDERATIONS

It should be immediately recognized by the profession that a physician cannot be successful if he has in his possession only a purely academic knowledge of the various phases of industrial medical work. The position of the physician in industry is unusual in the experience of the profession. He must first learn that his success in this field and the respect that he commands will result, not *ex officio* by reason of the fact that he possesses the title of doctor, but by the quality and type of his work. Unless he can apply his academic knowledge in a practical manner in full coordination with other branches of the industrial management, he will not receive the consideration, either executive or otherwise, that he should. He must learn that his leadership depends on his ability sufficiently to convince his associates of the soundness of his views and activities. This type of leadership is at the other extreme, however, of that which attempts leadership through the dignity of the title doctor. He must learn that many activities which are theoretically sound are not practical. He must learn, in other words, that there is a compromise between practical industrial medicine and theoretical hygiene, and unless he can with this realization apply theoretical medicine only so far as it is practical, or so far as he can make it of practical value, he will be unsuccessful. He must learn, too, that the respect that he commands from the industrial workers will depend solely on the quality of his work and on his personality.

I know of no other place than in an industrial plant where the medical graduate, essentially an individualistic practitioner, can acquire all this experience and knowledge. It is my opinion, therefore, that the industrial medical training should be partly theoretical and partly practical—that the theory be given in the classroom and that the practical be given in industrial plants. At least one half of the period of training should be spent actually in the plant, associated with the various departments with which the industrial medical work is so closely associated. He should understand the basic principles of employment man-

agement and personnel relations. He should become familiar with training and apprenticeship systems, with the view of there applying preventive medical work. He should know of the organization and conduct of continuation or skilled schools, and if he is thoughtful he will immediately see an opportunity for the practical application of medical supervisory work. He should understand trade tests and their relation to mental tests and psychology. He should understand job analyses, time study and shift systems, and their relation to his academic knowledge of fatigue. He should learn of accident prevention and safety-first organization and activities and consider their intimate relation to first aid medical work; physical examination, mentality, acuity of vision and such hygienic subjects as illumination, of which he has academic knowledge. He should acquire the necessary knowledge to analyze and thoroughly understand and deduct information from various labor force statistics, such as absenteeism, turnover, rates of pay as related to cost of living, housing, food—and hence health.

SOCIAL AND ECONOMIC ASPECTS

The student should understand the various systems of education of large groups and the basic problems presenting themselves in Americanization activities. He should know state insurance, group insurance, liability insurance and such actuary problems as present themselves in the mutual benefit associations and the pension plans. He should become acquainted with, understand, and enter into the local social and economic problems as such affect the industrial workers with whom he is concerned.

He should, in brief, have a sound medical education; ample practical experience in medical relief; a well rounded knowledge of preventive medicine; a thorough knowledge of vocational hygiene; an understanding of our present day social problems, and be able in the light of this knowledge to apply intensively to groups and in a practical manner the best that the medical profession has to offer to society.

ABSTRACT OF DISCUSSION

DR. J. W. SCHERESCHESKY, Washington, D. C.: The industrial physician has it in his power to influence enormously the health of a considerable portion of the community in which he is located. Many industrial communities have defective sanitary conditions which make the question of public health a problem of great difficulty. But industries are beginning to recognize more and more the dividends from keeping their men 100 per cent. well all the time. Not only is that good business, not only is it of value locally, but it is reflected in national prosperity and national productivity. The prosperity of the country, of the state or of the city rests on the productivity and activity of its man power, and the ability of its man power to produce rests on health. We must recognize this new group of industrial physicians who are endeavoring to carry on this type of work as powerful agents in the development of public health. I am sorry that the establishment of departments of industrial hygiene has been neglected in our municipalities. I know of only one city, among the first class cities, that has created such a department. The general tendency has been to leave industries pretty much to themselves, and any definite scheme of correlating the work of preservation of health in industrial plants and that of the city health department is very slow in being developed. The industrial physician forms the link by which the city health departments may be coupled with the industries. If they can be linked up they will be able together to make great progress in a general health movement. The

industrial physician will form the means by which industrial corporations themselves may be made to take an active interest in the sanitation of their own communities. The general attitude on the part of industrial units is pretty much as follows: We never mix in local politics because we want to be free from the suspicion of being connected with politics in order to advance our own purposes. As a matter of fact, that is a very short-sighted policy for industrial corporations to take, because most of them are large taxpayers, and they are more intimately concerned than anybody else in the health of the community. Therefore, the training of industrial physicians is one of great importance. Our great universities are giving their students an opportunity of entering a profession which gives a man a high degree of professional qualification, and places him in the situation of being able to influence for good the lives and health of a large number of our fellow citizens.

DR. EDWARD MARTIN, Philadelphia: The keynote of these most valuable papers and discussions today has been cooperation. We feel in Pennsylvania that the public health service means well, but its pull is not always with us, and sometimes it gives us little surprises. Public health service people are scattered around our state doing even they do not know what. No harm is done, as a rule, but we would like to work with the public health service, and we find it difficult sometimes to do so. The Red Cross is giving us splendid help and cooperation. Without it we could do little.

PARAPLEGIC MULTIPLE SCLEROSIS

ARCHIBALD CHURCH, M.D.

CHICAGO

When multiple insular sclerosis manifests itself by the classical signs of nystagmus, intention tremor and scanning speech, the diagnosis is self asserting. Such cases are extremely rare, and this triad of symptoms frequently is never fully developed or appears only after the lapse of years. Many cases persist clinically as optic atrophy, spastic paraplegia, primary lateral sclerosis, or vague organic and functional nervous maladies for long periods of time before the actual pathologic diagnosis and clinical differentiation are made. The frequent association of this condition with neurasthenia and as frequently with hysteria has long been recognized, but the organic process is too often overlooked under the protean subjective mask of the psychoneuroses.

A generation back, multiple sclerosis was considered an absolute rarity in this country, largely because only the classical picture was recognized. In some of its larvate and unusual forms it now furnishes a common clinical finding. On the point of possible increasing frequency of this disease I recently sent out a questionnaire to a limited number of American neurologists. All agree that they are seeing more cases than formerly, but all agree that they now recognize the formes frustes and aberrant types with a readiness that is somewhat of a recent acquisition. This is my own feeling in the matter, but I am convinced that the rank and file of the profession are not alive to the easy recognition of this dreadful disease. In the last three years in my private practice I find notes of thirty-two cases, in addition to which I might add an indefinite number seen in hospital practice. This group may perhaps be compared with the statistics of Unthoff, who was able to collect 100 instances in all the hospitals and clinics of Berlin in six years. But that was a decade ago, and only the advanced cases apparently were listed. Some recent observations tending to establish the etiology of the disease on a nonsyphilitic spiro-

chetal basis make one hesitate to deny the possibility or even the probability of an increasing incidence.

Considering that the lesions of multiple sclerosis are extremely widespread in the brain and spinal cord, without symmetry or systematization, it is quite surprising that the original clinical conception should have prevailed so completely and persisted so long. In many cases, symptomatically at least, the brain seems quite exempt; in others the cord is not materially disturbed; but in all, sooner or later both are implicated.

A number of clinical types may be encountered: first, the generalized classical form, which is infrequent, except as a terminal phase of the fractional forms; second, the cerebellar type, a rare early manifestation of the disease which tends to become full fledged rather rapidly; third, the optic atrophy type, which I believe is not uncommon and which only slowly eventuates into the generalized condition; fourth, the paraplegic or lateral sclerotic type, which appears to be the most common of all and which very slowly takes on the features of upper level and cerebral involvement, and fifth, a very rare monoplegic type.

I have no intention of drawing hard and fast lines, for they are far from justified in a disease the lesions of which are as diffuse and as uncertain as a shotgun pattern. However beginning, all types tend to eventuate in the fuller picture of the old description, and case records show the remarkable variations presented by cases at various times. To this observation must be added the tendency of the disease to advance in waves or crops and to recede often to a marked, but never, I believe, to an absolute degree. These clinical fluctuations are pregnant sources of false hope, and are particularly trying to the judicial mind attempting an evaluation of therapeutic effort.

While I desire to call immediate attention to the paraplegic and spastic form, it must be said that some degree of spasticity is the rule in all cases. This clinical type commonly begins with a weakness or clumsiness in one leg or foot. Patients not rarely describe a flapping of the foot in walking, or their friends call their attention to an irregularity in gait. This may improve or seem quite to recede after being present for weeks or months. Not infrequently it leads to stumbling or rather severe falls, and I have had patients who gained a reputation for falling in an unexpected and, to them, unusual fashion, for several years before other disability led to definite investigation.

Contrary to early descriptions, sensory disturbances both subjective and objective in character are not at all infrequent in this type of multiple sclerosis. Complaints of heaviness, numbness, coldness, and very rarely of more painful paresthesias have been encountered. I have actually demonstrated objectively a certain degree of coldness in one leg as compared with the other in two patients who complained of it, and suppose it must have depended on local circulatory disturbance, though no vascular inequalities could be demonstrated by manometer or detected by palpation.

Hypesthesia and girdling sensations of segment level distribution of very definite and persistent character have more than once given rise, in conjunction with other paraplegic features, to a diagnosis of pressure on the cord. Elsberg operated on one such patient, expecting to find a cord tumor, and I have had the same experience. Needless to say, the upper level symptoms were absent at the time, but in my

case gradually developed to a complete and illuminating degree.

Among the signs of the disease, when affecting mainly or only the lower extremities, are the pathologic reflexes—ankle clonus, Babinski's toe sign, intensified knee jerks, and last and most important of all, one-sided, partial or complete abolition of the umbilical reflex. The complete superficial abdominal reflex has been present in only one of my cases, and it may later disappear. With the absence of superficial abdominal reflexes, the deeper muscular reactions brought out by the percussion hammer are retained and often apparently increased, in parallel with other muscle and tendon responses.

An interesting and instructive observation is furnished by the lack of uniformity with which the reflexes are modified on the two sides. I have seen the abdominal reflex abolished on one side only, and in one case obtained from one lower quadrant of the abdominal area alone. I have seen ankle clonus on both sides disappear first on one side and, after a year, gradually on the other; but a Babinski once established seems to be persistent. Some patients give no toe movements of any kind from plantar stimulation, a feature emphasized years ago by Buzzard, who thought he saw in it a warning against a too ready diagnosis of hysteria.

The sphincter control in the late stages is not rarely weakened, and actual incontinence may occur. The gait shows all modifications of spastic, paraparetic and incoordinate conditions. Ready fatigue after a short walk, quickly yielding to a few minutes' rest, reminds one of intermittent claudication, but of course lacks the arterial factor.

To the lower level symptoms of the paraplegic type there are commonly added some of the cephalic manifestations of cerebral participation. Squints, double vision, marginal optic atrophy, irregularities of the visual field, cerebellar symptoms, intention tremor, speech defects, and even mental peculiarities, are some or all, in slight or marked degree, sooner or later observed.

The condition, therefore, as in all other manifestations of multiple sclerosis, becomes progressively worse, and complete disability the ultima. Fortunately, the patients suffer little, aside from the growing feebleness and helplessness, to which they progressively adjust themselves, and the disease does not in itself appear to be fatal.

The treatment of multiple sclerosis is a frequent source of disappointment. The iodids, mercury and arsenic have at times had strong supporters. Nonne and other European clinicians have given importance to Merck's fibrolysin, which I have tried very faithfully without in the end being able to share their favorable point of view. I am hopeful that a new era of therapeutic success may be shortly attained if the spirochetal origin of the disease is firmly determined and effective spirocheticidal remedies are discovered.

The contention of spirochetal origin started three years ago with Kuhn and Steiner¹ who, after injecting guinea-pigs and rabbits with the blood and serum of patients suffering from multiple sclerosis, found the spirochetes in some of the rabbits. These animals had presented motor symptoms suggestive of the human clinical manifestations. The spirochetes did not resemble those of syphilis, but rather the organism

1. Kuhn and Steiner: *Med. Klin.* 13:1007, 1917.

found in hemorrhagic icterus. They were spiral, often with a refracting terminal point, variable in form, and either extremity sometimes provided with a hairlike process. In 1918, Siemerling² found several similar spirochetes in the brain of a multiple sclerosis patient two hours after death. The next year Marinesco³ was able by intracerebral inoculations of spinal fluid from a patient to induce significant symptoms in guinea-pigs, and recovered spirochetes of the Kuhn-Steiner type from fluid taken from the fourth ventricle.

I have had several spinal fluids carefully searched for spirochetes without success, but have not yet repeated the animal experiments.

When we recall the difficulty of eradicating the syphilitic organism when seated in the parenchymatous nervous structures, a chill is given to enthusiastic expectations in regard to the manageability of this form of spirochete, even if it should be proved the essential cause of multiple sclerosis.

I have treated several cases with intensive courses of mercury, arsphenamin, neo-arsphenamin and the various iodids without being able to report any modification of the clinical course of the disease. As in syphilis, we must perhaps hope for better therapeutic agents.

1117 Marshall Field Annex.

THE TOXICITY OF NITROBENZENE

WITH REPORT OF A FATAL CASE

WILLIAM M. DONOVAN, M.D.

Instructor in Clinical Medicine, University of Wisconsin Medical School

MADISON, WIS.

Recently in THE JOURNAL there appeared three articles on the subject of acute nitrobenzene poisoning. The first, by Stifel,¹ referred to sixteen cases of nitrobenzene poisoning among army officers at Jacksonville, Fla., caused by a shoe dye. All men had recently worn freshly dyed shoes or puttees. The chief symptoms were marked cyanosis, headache, vertigo and tinnitus. Complete recovery occurred within from twelve to twenty-four hours in all cases. The second paper, by Scott and Hanzlik,² records some cases of nitrobenzene poisoning, with much the same symptoms as in the first article, due to the imbibition of "denatured" alcohol; here, too, no fatalities occurred. As a result of their observations and those of Stifel, these authors express the opinion that "this 'denaturizing' agent is relatively harmless." More recently, Sanders³ reported a case of nitrobenzene poisoning with cyanosis, a rapid recovery being made.

That nitrobenzene may be quite toxic for man has been attested by many German writers, and by Cushny,⁴ who states that it may cause "a grayish-blue cyanotic color of the skin and visible mucous membranes, often with nausea, vomiting, great muscular weakness, marked dyspnea, delirium and some convulsive movements of the face and jaws, less frequently of the whole body. Total unconsciousness and coma

are followed by arrest of the respiration." According to Cushny, the symptoms are due mainly to blood changes (deformation and destruction of red cells; formation of methemoglobin and nitrobenzene hemoglobin) and to a central nervous action—stimulation followed by depression.

Fatal cases are not unknown, among which may be mentioned that reported by Blythe (quoted by Stifel) of a man who died following the accidental spilling of nitrobenzene on his clothing.

As may be surmised, most cases of acute poisoning from this substance, as recorded in the literature, were due to its absorption through the skin or pulmonary alveoli (inhalation), as in Blythe's case of fatal poisoning. In Scott and Hanzlik's cases it took place presumably from the gastro-intestinal tract, which, it may be argued, had some mitigating influence on its fatal toxic properties.

REPORT OF CASE

The case reported herewith resulted fatally, and was apparently uncomplicated nitrobenzene poisoning in which the poison was swallowed.

In 1917, a middle-aged white man was brought by patrol into the receiving ward of the University Hospital, Philadelphia, in coma. A striking feature was the marked ashen-gray cyanosis, which was more intense than that usually seen. There was a very strong odor of nitrobenzene (shoe polish) about the patient, especially in his mouth. Respirations were about ten a minute. Gastric lavage yielded a fluid of similar odor in which nitrobenzene was detected by chemical means. In spite of vigorous stimulation and the use of the pulmotor with attached oxygen tank, the patient died about forty-five minutes after entering the hospital. He did not regain consciousness. Death was apparently respiratory—the breathing becoming less and less frequent. No spectroscopic examination of the blood for methemoglobin or nitrobenzenehemoglobin was made. It was never learned in what medium the poison was taken.

COMMENT

The details of this case are necessarily meager because of its emergency character—the patient not having been "admitted" and therefore no history written. The facts are simply culled from memory. It is possible that some other poison was taken simultaneously. I simply wish to report it as a possible case of uncomplicated nitrobenzene poisoning with fatality, in which the substance was apparently swallowed.

CONCLUSION

Nitrobenzene may be more toxic than is indicated by Scott and Hanzlik.

University Infirmary.

The Study of Surgical Diseases.—There can be little question that the diseases spoken of as surgical (because operative technic is employed in treating them) are of such great importance and the technic of their therapy has become so specialized, that one or more clinics of the department should be devoted to the study of these diseases. This does not mean, however, that the methods employed in studying these diseases differ from those used in studying any other group of diseases. Exophthalmic goiter is the same disease whether we treat it by removal of the thyroid or by rest and drugs. Whether we call the professor who studies especially those diseases in which the chief therapeutic procedures are operative, a professor of surgery or a professor of medicine, is unimportant so far as the principle is concerned. His methods should be those of the professor of medicine, and the surgical clinic should be exactly like the medical clinic with the addition of facilities for employing complicated operative procedures.—Rufus Cole, *Science*, April 2, 1920.

CARDINAL FACTORS IN PULMONARY EDEMA

The menace of the poisonous war gases is no longer with us. Perhaps the suffering and deaths which these frightful agencies of destruction caused will not have been entirely in vain if the experience gained in the extensive study of war gas poisoning can be utilized with advantage in the relief of disease among mankind. The consensus among the investigators who concerned themselves with the pathology of the acute effects of the commonest war gases is that the prominent feature is a typical pulmonary edema. This is also a distressing symptom encountered in every-day clinical experience; hence whatever new may be learned about it has more than merely war-time application.

In a lecture before the Harvey Society last year, Underhill¹ directed attention to the circulatory conditions attending the formation of the pulmonary edema due to lethal war gases. An early period of blood dilution is followed by an interval during which the blood rapidly becomes concentrated to a point far beyond the normal value, and remains near this level for some time. Eyster showed that at this stage the heart may be markedly decreased in size, a result which would presumably tend toward decreased efficiency of this organ and lead to an inadequate circulation. The striking loss of fluid from the blood by transfusion into the tissue spaces and into the air passages of the lung may lead to reduction in blood volume, hemoglobin concentration and decrease in heart size to somewhat extreme degree, as has lately been reemphasized by Meek and Eyster² of the University of Wisconsin. They agree with Underhill that death ultimately results from decreased oxygenation of the pulmonary blood and from oxygen starvation of the tissues due to decreased blood volume, the latter probably being the more important.

Impaired respiratory function of the blood owing to deficiency in corpuscles and oxygen-carrying hemo-

globin is emphasized daily in medical practice. The possibility of an impairment with the same outcome but due to decrease of the circulating medium as a whole has not been so generally recognized. Underhill has proposed that as a fundamental principle in the therapeutics of such edemas the blood concentration should be diminished or prevented, if possible. This may be accomplished experimentally by infusion of sodium chlorid solution, by intraperitoneal injections of the latter, and even by oral administration of water. The lack of oxygen due to a reduced circulation further impaired by the increased viscosity of the concentrated blood can be remedied in part by administration of oxygen. This is, of course, a palliative, as it cannot reduce the edema or restore alveolar epithelium if the latter has been damaged. It may serve, however, to help avert tissue asphyxiation until the fundamental defect of decreased blood volume can be remedied. It will be interesting and important to learn in what conditions this more recently recognized blood concentration occurs in pulmonary edema during times of peace. The possibilities of therapy suggested for the alleviation of suffering from the edema due to war gases can then perhaps find application.

THE SPHINCTER OF THE COMMON BILE DUCT

The opening of the common bile duct into the duodenum is ordinarily closed by a sphincter. On this account the bile, which is formed more or less continuously by the liver, discharges into the bowel only at periods when the muscle closing the orifice of the duct is relaxed or inhibited. In the intervals between the periodic passage of bile into the intestine, the fluid secreted is stored away in a quiescent gallbladder. Meltzer¹ has compared the mechanism of the gallbladder with that of the urinary bladder. In the latter the collection and evacuation of the urine is controlled by the antagonistic activities of two muscles of the bladder. During the accumulation of urine in the bladder, the detrusor muscle is relaxed and the sphincter is tonically contracted; whereas during micturition, the reverse takes place: the detrusor contracts and simultaneously the tonus of the sphincter at the neck of the bladder becomes inhibited. Comparably, according to Meltzer, the muscle fibers of the gallbladder and those about the papilla of Vater are antagonists. During the absence of flow into the bowel, the muscle fibers in the papilla are contracted and those of the gallbladder are inhibited; during the discharge, the gallbladder contracts and Oddi's muscle is relaxed; the bile has then no other way out but into the duodenum.

If this conception of the functions of the bile-storing organ leading to periodic discharge of bile into the

2. Meek, W. J., and Eyster, J. A. E.: Experiments on the Pathological Physiology of Acute Phosgene Poisoning, *Am. J. Physiol.* **51**: 303 (March) 1920.

1. Meltzer, S. J.: The Disturbance of the Law of Contrary Innervation as a Pathogenetic Factor in the Diseases of the Bile Ducts and the Gallbladder, *Am. J. M. Sc.* **153**: 469 (April) 1917.

duodenum is correct, it is obvious that failure of appropriate action in any part or disturbance in the nice correlations involved may lead to pathologic consequences. The occurrence of stasis through imperfect behavior of the sphincter closing the common bile duct is at once suggested; and the mention of stagnation of the bile at once calls to mind secondary complications that may ultimately lead to mechanical obstruction in biliary flow.

In view of these considerations, it is surprising that so little attention has been paid to the physiology of the sphincter which Oddi² described, in 1887, as occurring at the termination of the common duct. Until recently, many clinicians have actually declined to attach any importance to the muscular structure to which we have referred. As recently as 1900 Naunyn,³ a recognized expert in the field of biliary pathology, regarded it as worth while to emphasize the significance of the choledochoduodenal sphincter in connection with the filling of the gallbladder, and the possible dangers of an exaggerated tonus in the musculature. Recently, Mann⁴ of the Mayo Clinic has shown, what might perhaps be suspected from physiologic reasoning, that the tonus of the sphincter at the duodenal end of the common bile duct is decidedly more vigorous in species that have a gallbladder than in animals that normally lack this organ. In the latter species, the sphincter would not withstand pressure of more than slight intensity at the most. While anatomic studies have shown that a sphincter is present in each species lacking a gallbladder, the sphincter does not seem to function appreciably. Obviously, when there is lack of a gallbladder for storage of bile, stasis produced by a resistant sphincter might soon induce serious difficulties.

A study which Reach⁵ of Vienna has lately published shows anew that the sphincter of the common bile duct can be influenced reflexly in various ways. According to him, filling the stomach tends to maintain a closed duct orifice; as the stomach empties, the sphincter relaxes and the bile is discharged. Whatever inhibits this sphincter and empties the bile passages must reduce the pressure in the gallbladder, a fact of importance when it is desired to facilitate the healing of fistulous openings in this organ. According to Reach, drugs also can act on the tonicity of the sphincter; some, like papaverin and scopolamin, inhibiting, while others, such as morphin, are able to stimulate the muscle to close the orifice. These tentative pharmacologic findings deserve to be elaborated to the point at which their possible application in human therapy can be ascertained; for occasional

instances undoubtedly arise in which failure of relaxation of the sphincter of the common duct, particularly during contraction of the gallbladder, needs to be counteracted.

THE RÔLE OF LYMPHATICS IN PNEUMONIC INFECTION OF THE LUNGS

In a recent issue,¹ evidence for the bronchiogenic character of the lobar pneumonia produced experimentally in monkeys by Blake and Cecil was reviewed. It is apparent from their studies that the respiratory tract, rather than bacterial invasion of the blood, is the primary factor in the genesis of the disease so closely related to the comparable malady in man. When the lining mucosa of the trachea is damaged and the protective mechanism of the respiratory tract is impaired, a portal of entry for micro-organisms associated with pneumonia is obviously afforded. This is undoubtedly what happens as a consequence of the inhalation of pulmonary irritating gases, as has been pointed out by Winternitz.²

Blake and Cecil³ produced their experimental results by intratracheal inoculation of the animals through needle puncture. They apparently assumed that no damage was produced by this procedure; hence the pneumonia seems to have started despite an unharmed and normally adequately protective mucosa. Winternitz, Smith and Robinson⁴ of the Yale School of Medicine have pointed out, however, that in such inoculations the needle, though sterile on entry, is unquestionably infected when it is withdrawn, and consequently a possible path of infection to the lung may be found elsewhere than through the lumen of the trachea.

In harmony with this assumption, the submucosa of the trachea and bronchi has been demonstrated by the New Haven investigators to furnish a pathway of infection to the lung. It contains a rich plexus of lymphatics prominent everywhere and devoid of valves. There is a continuity throughout this lymphatic system so that bacteria which once find their way into it can easily spread. Although it thus affords a direct pathway of infection to the lung, Winternitz and his colleagues allege that it may also serve as a protective mechanism against pulmonary infection; for the drainage of the submucosa of the trachea and bronchi is largely diverted as the lung is approached to the protecting regional lymph nodes.

The spread of infection through lymphatic channels is probably more common than has been appreciated by most clinicians. The investigations of recent years

have shown that progressive pyelonephritis is by no means always, if indeed it is commonly, dependent on direct transference of the micro-organism backward along the urinary channels from the distal parts of the latter first invaded. The little recognized lymphatics of the urinary organs may serve in this case as the paths of bacterial advance independent of the urine in the ureters. A further analogy is seen in the streptococcus lymphangitis of the finger which sometimes follows a needle puncture.

FACTORS AFFECTING THE CONSERVATION OF PROTEIN IN THE BODY

Soon after the signing of the armistice, when the first reports of the food stringency and the resulting malnutrition of the population of the Central Empires reached this country, the statements were looked on by many as a continuation of propaganda intended to secure amelioration of peace terms. Subsequent investigations have, however, furnished a verification of the threatening conditions that still exist abroad. Thus, in a recent issue of *THE JOURNAL*,¹ an experienced observer wrote that of 4,500 medical men in Vienna at least 90 per cent. are working on half rations, and many are actually on the point of starvation. Major Mason² of the Sanitary Corps, U. S. Army, reviewing the situation, remarks that "for the first time in history the world at large faces a universal food shortage. Heretofore scarcity of food has been only local, the famines of India and Ireland being well-known examples, and in these cases it was always possible for other countries to get food to the lands of shortage. Today there seems reason to believe that in the whole world there is not all the food which could be consumed by all the people."

The undernourishment that has ensued abroad involves not only reduction of fat but also a loss of protein from the body. Restoration of adequate nutritive conditions will require renewal of the store of protein, that foodstuff which the war stringency has made the scarcest of all. Recently it has been asserted³ that the mineral metabolism of the body plays an important part in the intensity of the protein destruction, the contention being that potential acidity of the diet tends to increase, whereas a preponderance of base-forming food tends to curtail the protein breakdown.

If this assertion should prove true, its bearing on the nutrition of those restricted to minimal intakes of protein is obvious. Careful consideration of the acid-base relationships of the diet would then be desirable to assure a maximum conservation of bodily tissues

when the supply of protein is below the optimum. A reinvestigation of the question by Jansen⁴ in Friedrich Müller's clinic in Munich disposes of the assertion. He has found that even the addition of inorganic acid to a diet of low protein value does not alter the output of nitrogen in the urine. The fecal output may be slightly augmented, owing to the action of acid in provoking alimentary secretions; but, broadly speaking, under usual dietary conditions the acid or basic potentialities of the food are without practical significance in the maintenance of protein equilibrium. The partition of nitrogen in the urine, as indicated by greater or less participation of ammonia in its output, may be altered; not, however, the total metabolism. In times of stress, therefore, protein is best conserved by the liberal ingestion of carbohydrates, not by a readjustment of the acid-base balance of the diet. And this is what the classic students of nutrition have long taught.

Current Comment

ARCHIVES OF SURGERY

For a number of years the proposal to publish a high-class journal devoted to surgery has been before the Board of Trustees of the American Medical Association. The final decision to publish such a journal has been delayed from time to time, partly because of the war, and partly because some believed there was no real need for a surgical journal. But criticism has been advanced that American surgery is not developing symmetrically, that the technical side—operative surgery—has been highly developed at the expense of the investigative and philosophical sides, and that there is a real need for a journal to represent these phases of surgery as a science. The Board of Trustees finally decided to publish such a journal, and the action of the Trustees was approved by the House of Delegates at the New Orleans meeting. At the outset it will be issued bimonthly. Papers dealing with experimental work will be accepted and space allowed for protocols which have a direct bearing on, or an explanatory relation to, the problem considered. Articles will be welcomed which deal with clinical research in the hope of stimulating more careful and closer clinical examination. The value of laboratory methods has been rightly emphasized, but unfortunately in many instances to such an extent that the ability and desire to make close clinical observations have been lessened or lost. The value of monographic publication cannot be denied, and whenever a monograph is of sufficient value an entire number, if necessary, will be given to it. In a word, this new journal—*Archives of Surgery*—will be devoted to the advancement of American surgery, in the same way as the other special journals published by the American Medical Association are devoted to the advancement of the specialties they represent: Internal

2. Mason, C. C.: German Nutrition, 1914-1919, *Bull. Johns Hopkins Hosp.* 31:66 (March) 1920.

3. Berg, R.: Die Nähr- und Genussmittel, Dresden, 1913; Die Bewertung der Säureverteilung im Harn. *München. med. Wchnschr.* 1914, No. 23. Röse, C., and Berg, R.: Ueber die Abhängigkeit des Eiweissbedarfs vom Mineralstoffwechsel, *ibid.*, 1918, No. 37.

4. Jansen, W. H.: Zur Frage der Abhängigkeit des Eiweissstoffwechsels vom Säuren-Basengehalt der Nahrung, *Ztschr. f. klin. Med.* 88:221, 1919.

Medicine, Diseases of Children, Neurology and Psychiatry, and Dermatology and Syphilology. The personnel of the editorial board consists of Dr. Hugh Cabot, professor of surgery, University of Michigan, Ann Arbor; Dr. Thomas Cullen, professor of gynecology, Johns Hopkins University, Baltimore, Maryland; Dr. William Darrach, professor of surgery, Columbia University College of Physicians and Surgeons, New York City; Dr. Evarts A. Graham, professor of surgery, Washington University, St. Louis, Missouri; Dr. Dean D. Lewis, professor of surgery, Rush Medical College, Chicago, and Dr. W. J. Mayo, the Mayo Clinic, Rochester, Minn. The positions in American surgery of the group of men who have accepted the responsibility for the editorial standard of the new journal will indicate its scientific scope and character. Coming from the press of the American Medical Association it is unnecessary to say that it will be, mechanically and typographically, equal to any similar publication in any language. This will especially apply to the illustrations: drawings, photomicrographs, half-tones, in color or in black and white, will be liberally used. The first number will appear, July 1.¹

STOMACH GASES AND AEROPHAGY

The occurrence of gases in abnormal quantities in the gastro-intestinal tract is familiar through the frequent clinical observation of meteorism and tympanites. Most of the available analyses of intestinal gases indicate that nitrogen, methane, hydrogen and carbon dioxid may be present, while hydrogen sulphid and oxygen are sometimes added to the list. It has generally been assumed that the nitrogen and oxygen represent residual parts of atmospheric air swallowed with food; carbon dioxid may be derived from the blood, whereas the other gases mentioned are products of fermentative changes induced by micro-organisms always present in the alimentary canal. In aerophagy, or the increased swallowing of air, sometimes occurring as a nervous performance in hysterical persons, part of the gases may be eructated again, though frequently some of the air passes farther into the bowel. The clinician regards the presence of the gases in the intestine as an undesirable symptom that needs therapeutic attention whenever the local accumulations cannot escape properly and tend to produce distention. Aside from this aspect of the subject, little consideration has been given to the occurrence of gases in the stomach.² By studying the content of carbon dioxid in the stomach gases of air-swallowing infants, Ylppö³ came to the conclusion that the carbon dioxid at least was derived by diffusion from the blood. Further investigations on adults have demonstrated that various gases, whether represented by atmospheric air, pure

oxygen or carbon dioxid, when introduced even in considerable volume into the stomach, soon come into equilibrium with the blood gases as represented in the alveolar air. Thus, at the end of an hour the percentage of carbon dioxid and of oxygen in the stomach gases and alveolar air are usually almost identical. When air has been introduced into the stomach, flatulence will result because of the residual nitrogen. This is not the case when carbon dioxid is introduced; and with oxygen it happens only when the intake is very large—more than 1,000 c.c. As the gases have thus been shown to behave toward the alimentary wall in accord with physical laws of diffusion, it has been estimated that not negligible amounts of oxygen might be introduced into the body by way of the gastro-intestinal tract under circumstances in which pulmonary respiration is severely impaired by disease. At best, however, the total quantity would represent only a small fraction of the day's need of the indispensable element.

A PEDIATRICIAN OF THE SECOND CENTURY

According to a recent publication,¹ during the reign of Trajan, between 110 and 130 A. D., Rome was the home of the greatest obstetrician and pediatrician of antiquity—Soranus of Ephesus. At the eleventh International Congress in Rome, 1895, I. V. Troitski, writing in Russian, compared in parallel columns the practices of Soranus with the teachings of authorities of his own time. The survey of what Soranus knew is again an appeal for the study of medical history, for if we exclude innovations resulting from our knowledge of antiseptics, the practical advice which he gave might well serve for modern use. His instructions as to breast nursing and the care of the wetnurse are delightfully worded. "The essential mental qualities of a good nurse," he says, "are patience, common sense, good nature or gentleness and neatness." These essential qualities have not changed. Again, "Feeding at irregular intervals and often during the day, and especially during the night, may be the cause of sickness in the infant." Every pediatrician will confirm this view. His suggestions as to the causes of crying, and how to differentiate between the various causes, appear much the same as those in our modern "baby books." None of the earlier writers on medical subjects so well appreciated, as did Soranus, the importance of feeding in the care of the infant. He made one suggestion typical of the customs of his time, namely, that wetnurses be employed rather than having the mother nurse her own infant. This advice was based on the theory that the mother might be physically unable, after parturition, to nurse the infant, and no doubt also on the fact that mothers, in his time, were notoriously dissipated. Parenthetically, it may be remarked that Soranus seems to have had a wealthy clientele.

Dust and Health.—Dust from abrasive materials does not render a worker unconscious or cause him visible distress, but it accomplishes its harmful effects without unduly alarming or exciting any one.—P. M. Holmes, *Pub. Health Rep.*

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ILLINOIS

Personal.—Dr. Milton Jacobs of the staff of the Elgin State Hospital and who has also had charge of the examination of subnormal children of Elgin schools has resigned and will enter general practice in Elgin.—Dr. Arthur F. Stotts, Galesburg, who has been under treatment in a hospital since May 8, has returned home much improved.

Chicago

Surgeons Elect Officers.—At the annual meeting of the Chicago Surgical Society, June 4, Dr. William Fuller was elected president; Dr. Vernon David, vice president; Dr. Frederick G. Dyas, secretary, and Dr. Charles F. Sawyer, treasurer.

Legion Post Dinner.—Chicago Medical Post No. 216, American Legion, announces an informal round-up dinner to be given June 23, at 6:30 p. m. in the gold room of the Congress Hotel, at which Dr. Joseph B. Miller will officiate as toastmaster.

Physicians Ask Health Plan.—The Chicago Community Trust is asked to undertake a city plan of health to include all phases of public health and provision for the care of the sick and physically disabled by resolutions adopted at the meeting of physicians and health workers at the Chicago Club, May 28. Among those who spoke on this occasion were Drs. James B. Herrick, Edwin W. Ryerson, Harry E. Mock, E. O. Jordan, Joseph B. DeLee and John Ritter.

KENTUCKY

Alumni Clinic.—At the week of clinics held in honor of the alumni of the medical department of the University of Louisville, from May 31 to June 5, there were 285 members registered, and 376 attended the banquet the evening prior to the commencement exercises, at which a class of twenty-nine received diplomas. On the first evening, a joint meeting of the Jefferson County Medical Society and the alumni association was held, at which Dr. Frank B. Wynn, Indianapolis, delivered an address on "The Respiratory Sequelae of Influenza, a Clinico-Pathologic Discussion."

MARYLAND

Memorial at Fort McHenry.—Impressive Memorial Day exercises at Fort McHenry were held at the base of the old flag staff in the south fort on May 31. The ceremony closed with the lowering of the colors and the sounding of "taps." In addition to being a tribute to the soldier dead, the "taps" also sounded the passing of U. S. Army General Hospital No. 2, whose official existence ceased on that day. Dr. Thomas R. Payne, Corbett, will be superintendent under the new régime. Major James E. Baylis, M. C., U. S. Army, will continue as commanding officer.

Health Conference.—At the invitation of Dr. John S. Fulton, head of the state department of health, health officers throughout the state met at the Medical and Chirurgical Faculty Building, Baltimore, for a two-day convention, June 7 and 8. Dr. William H. Welch; Dr. Hugh H. Young; Miss Nellie F. Oxley, division director of public health nursing, Potomac division of the Red Cross; Dr. Paul B. Johnson, director of the department of health service, Potomac division of the Red Cross; Dr. William A. Bridges, medical representative, Maryland Tuberculosis Association; Dr. John M. T. Finney; Prof. Edward F. Webb and William J. Holloway, state superintendent of rural schools, were among the speakers.

Personal.—A portrait of Dr. William H. Welch, president of the University Club of Baltimore, was presented to the club at its last monthly meeting.—Dr. John M. T. Finney, Johns Hopkins University, was decorated with the insignia of an officer of the French Legion of Honor on behalf of the French government by the French military attaché in Washington, D. C., June 3. The decoration was given in recognition of Dr. Finney's ministrations to French soldiers in American hospitals overseas during the war.—Surg. Gen.

Hugh S. Cumming, U. S. Public Health Service, was recently in Baltimore, accompanied by Drs. Claude H. Lavinder, William G. Stimpson and Richard H. Creel; and later with the mayor, Drs. John M. T. Finney, C. Hampson Jones, city health officer, and Winford H. Smith, superintendent of the Johns Hopkins Hospital, visited Fort McHenry to make a survey of the hospital facilities. The city authorities want a portion of the equipment at the fort for municipal hospital purposes, temporarily, if it cannot be arranged as a permanent thing, and the survey was made with this in view.

MASSACHUSETTS

Centenary of Medical Missions.—The centenary of the founding of medical missions was celebrated, May 9, at the all-student rally held in the new Old South Church, Boston, when President Ellen W. Pendleton of Wellesly College, Cyril Haas, Frances J. Heath, Cora J. Patton and Mrs. Henry W. Peabody told the story of medical missions from the time, in 1819, when Rev. John Scudder and his wife sailed from America to begin their work in Ceylon.

Personal.—Dr. Benjamin White has been appointed director of the division of biologic laboratories of the Massachusetts State Department of Health, succeeding Dr. Milton J. Rosenau. Dr. White has also been appointed lecturer in immunology in the Massachusetts College of Pharmacy, and assistant in the department of preventive medicine and hygiene at Harvard University Medical School.—Dr. Lawson G. Lowrey, chief medical officer of the Boston Psychopathic Hospital for two years, has been appointed assistant professor in the psychopathic department of the University of Iowa, Iowa City.

MISSOURI

Eye, Ear, Nose and Throat Section Organized.—An eye, ear, nose and throat section of the Buchanan County Medical Society was organized at St. Joseph, March 10. Dr. Pierre I. Leonard was elected chairman, and William L. Kenney, secretary of the section.

Personal.—Dr. and Mrs. Clinton B. Ellis, Kansas City, have sailed for Europe.—Dr. James W. Bruton, Ozark, has been appointed deputy health commissioner for Christian County.—Dr. L. Paul Forgrave, St. Joseph, has been elected a member of the board of health of St. Joseph.

NEW JERSEY

Illegal Practitioners Fined.—A report states that John W. Glover of Bridgeton, who claimed to be a practitioner of the exanthematic method of cure of all chronic diseases, pleaded guilty to the charge of practicing medicine without a license and was fined \$200.—Paul Schmidt of Newark was also found guilty of practicing medicine without a license and paid a fine of \$200.

NEW YORK

Personal.—Dr. Clarence E. Cobb, Alfred, has been appointed superintendent of the Steuben County Tuberculosis Hospital, succeeding Dr. Elliott I. Dorn, Cassadaga.—Dr. Manna Mary Rohn, health officer of the Lake George Health District, is carrying on a complete sanitary survey of the shores of Lake George.

New Publication.—The state department of health began in March the publication of a monthly periodical known as the *Monthly Vital Statistics Review*, which is edited by Dr. Otto I. Eichel, director of the division of vital statistics of the board. The periodical is an attempt at a much more elaborate presentation of current official vital statistics than has heretofore been tried in this country. It presents a comment on the trend of vitality in the state, with tables showing influenza and pneumonia deaths, and death rates; deaths from all causes; general death rates given by months compared with previous years; infant mortality from 1913 to 1920; deaths of infants under 1 year of age; deaths and death rates from pulmonary tuberculosis, 1913-1920, and abstracts from the Weekly Health Index of the United States Bureau of Census.

New York City

Personal.—Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research, will represent the United States at the first formal meeting of the medical advisory board of the League of Red Cross Societies at Geneva, July 5.

New Brooklyn Hospital Dedicated.—The Brownsville and East New York Hospital, located at East Ninety-Eighth Street and Rockaway Park, which was erected and equipped

at a cost of about \$325,000, has been dedicated and is ready to receive patients.

Sanitary Code Affecting Drugs Amended.—Subdivision 2 of Section 116 of the Sanitary Code has been amended so that any drug is regarded as adulterated "if its strength or purity falls below, or its strength is in excess of, the professed standard under which it is sold."

Physician Fined.—Dr. Arthur H. Stern, Manhattan, arrested in a raid, July 19, 1919, by revenue agents, charged with violation of the Harrison antidrug act, is said to have pleaded guilty before Judge Angus M. Hand, May 26, and to have been fined \$5,000, and committed to the custody of the United States marshal for one day.

Registration of Patent and Proprietary Medicines.—Owing to enforcement of Section 117 of the Sanitary Code, the Division of Patent and Proprietary Medicines of the Bureau of Food and Drugs of the New York City Department of Health, has recently had a large number of patent and proprietary preparations submitted for registration, and a number of preparations have been withdrawn from sale, as the claims made for them were exaggerated and false and the accompanying statements misleading. During the influenza epidemic, pharmaceutical manufacturers took advantage of the anxious state of the public and advertised various products for the prevention and cure of the disease. These advertisements in the daily papers and elsewhere were ordered discontinued under pain of prosecution by the health department, and the orders have been promptly obeyed.

Bulletin of the New York Association for Medical Education.—This organization, incorporated under the laws of New York State in August, 1919, for the purpose of expanding medical education for students and graduates of medicine has issued its first bulletin, which consists of a report of the subcommittee on ophthalmology and otolaryngology, of which Dr. James F. McKernon is chairman, and Drs. Arnold Knapp, Cornelius G. Coakley and Frederick Whiting are members. This report formulates the requirements necessary to educate and train physicians who desire to become specialists in the department of ophthalmology, rhinolaryngology and otology. All the details of a standard course in this department and also of graduate courses of instruction are outlined and are now available. Those interested in these courses can obtain further information at the headquarters of the association, 17 West Forty-Third Street, New York.

NORTH CAROLINA

Hospital to Be Built.—The Crowell Urological Clinic, Charlotte, has purchased a lot adjoining the Charlotte Sanatorium on which to build an office and hospital building. The hospital portion of the building will be divided into the urologic and dermatologic departments of the sanatorium.

OHIO

Illegal Practitioner Fined.—A report from Ohio states that on May 21 George Gueth, Sidney, pleaded guilty to practicing medicine without a license and was fined \$25 and costs.

Health Commissioners Elect Officers.—At the meeting of health commissioners of the state held in Columbus, May 12 to 14, the following officers were elected to serve on the commission to enforce milk and dairy regulations for all cities and counties throughout the state: president, Dr. William T. Peters, Cincinnati; vice presidents, Drs. John A. Kappelman, Canton, Oral J. Tatje, Portsmouth, and Harley J. Powell, Bowling Green, and secretary-treasurer, Dr. Rush R. Richison, Springfield.

PENNSYLVANIA

Philadelphia

Personal.—Dr. William W. Keen has been elected an honorary fellow of the Royal Society of Medicine, London, and of the American Surgical Association.—Dr. Edward T. Reichert, professor of physiology in the Medical School of the University of Pennsylvania, has retired from active service.—Dr. and Mrs. James A. Irwin sailed for France, June 12.

University Graduate School Budget.—Trustees of the University of Pennsylvania have decided to take steps, further to equip and advance the work of the university graduate school of medicine. At the last meeting of the board of trustees, a budget of \$158,097.37 was approved to meet such

expenses as are not provided in the regular income of the graduate school of medicine.

Phipps Institute to Continue.—Dr. Charles J. Hatfield, executive director of the Henry Phipps Institute, announced on May 29 that the result of the recent drive for funds made by that institution is such as to assure the continuation of the institution until July 1, 1921. This is made possible by the liberality of the family of Henry Phipps who have made available the interest on the \$500,000 recently promised by them for the endowment fund. The sum of money contributed in Philadelphia is approximately \$45,000 to date.

Jefferson Alumni Banquet.—The annual banquet of the alumni association of Jefferson Medical College was held in the ballroom of the Bellevue-Stratford Hotel, June 4, with 300 present. Dr. S. Solis Cohen, president of the association, presided, and addresses were made by the following men: Dr. Albert E. Austin of Connecticut; Drs. F. X. Dercum, Franklin Spencer Edmonds, William Potter, president of the board of trustees; J. K. Weaver of Norristown of the class of 1867, the oldest graduate present, and Dr. Hobart A. Hare.

Symposium on Hygiene and Physical Training Teaching.—At the stated meeting of the College of Physicians of Philadelphia a symposium was held on the teaching of personal hygiene and physical training in our public schools, colleges and universities. Dr. Edward Martin, commissioner of health of Pennsylvania, Harrisburg, opened the symposium on the teaching of personal hygiene in the public schools of Pennsylvania, and Dr. R. Tait McKenzie, professor of physical education in the University of Pennsylvania, spoke on "The Importance of Teaching Personal Hygiene and Physical Education in our Colleges and Universities."

SOUTH CAROLINA

New State Officers.—At the annual meeting of the South Carolina Medical Association, held in Greenville, the following officers were elected: president, Dr. Washington P. Timmerman, Batesburg; vice presidents, Drs. Miles J. Walker, York, William A. Boyd, Columbia, and William W. Fennell, Rock Hill, and secretary, Dr. Edgar A. Hines, Seneca (reelected).

Personal.—Dr. George T. Swandale has resigned as a member of the Greenville Board of Health and has been succeeded by Dr. Charles W. Gentry.—Dr. Jean B. Laborde, Columbia, has been elected city physician, succeeding Dr. Clarence E. Smith, elected city health officer of Greenville.—Dr. T. W. Smith has been elected a member of the board of health of Newberry, succeeding Dr. James K. Gilder, deceased.

Tuberculosis Association Meeting.—At the annual meeting of the South Carolina Tuberculosis Association, in Columbia, April 30, under the presidency of Dr. Reed Smith, Columbia, the following officers were elected: president, J. Nelson Frierson, Columbia; vice presidents, Drs. Richard M. Pollitzer, Charleston, and Ernest Cooper, Columbia; secretary, Dr. Reed Smith, Columbia, and treasurer, A. S. Manning, Columbia (reelected).

New Medical Board.—The governor has reappointed the following as the state board of medical examiners under the new act passed in the last session of the general assembly: first district, Dr. Joseph T. Taylor, Adams Run; second district, Dr. Josiah S. Matthews, Denmark; third district, Dr. Frank M. Lander, Williamston; fourth district, Dr. Baxter M. Haynes, Spartanburg; fifth district, Dr. Joseph R. Miller, Rock Hill; sixth district, Dr. George B. Edwards, Darlington; seventh district, Dr. Julius H. Taylor, Columbia, and state at large, Dr. A. Earle Boozer, Columbia.

SOUTH DAKOTA

Guilty of Manslaughter.—The jury considering the case of manslaughter against Dr. Oscar H. Clark, Newell, charged with the death of Alice Lenth, following an illegal operation, is said to have returned a verdict of guilty, May 17.

Clinic Building Ready.—The new Sioux Falls Medical and Surgical Clinic building, Eleventh and Minnesota Avenue, is expected to be ready for occupancy this month. The building which has been constructed at a cost of about \$100,000, is two stories in height and will be occupied by eight physicians of Sioux Falls.

State Society Meeting.—The South Dakota State Medical Association held its thirty-ninth annual session in Sioux Falls, May 18 to 20, under the presidency of Dr. Robert D. Alway, Aberdeen, and the following officers were elected:

president, Dr. Harry T. Kenney, Pierre; vice presidents, Drs. George S. Adams, Yankton, and Gilbert G. Cottam, Sioux Falls; secretary-treasurer, Dr. Frederick A. Spafford, Flaudreau (reelected); delegate to the American Medical Association, Dr. Robert D. Alway, Aberdeen, and alternate, Dr. Theodore F. Riggs, Pierre. Aberdeen was selected as the next place of meeting.

TEXAS

Personal.—Dr. Douglas Largen, San Antonio, has been appointed assistant state health officer and has been placed in charge of the division of venereal diseases.—Dr. J. Q. Durham, Memphis, was seized with cerebral hemorrhage while driving his car, April 25, and is still seriously ill.—Dr. H. H. Terry and Julian Murchison have been appointed assistant city health officers of Fort Worth.

New Officers of State Society.—In addition to the officers of the State Medical Association of Texas, published in THE JOURNAL, May 8, page 1335, the following officers were elected: vice president, Dr. Willis J. Pollard, Kaufman; secretary, board of trustees, Dr. W. R. Thompson, Fort Worth (reelected); councilors, second district, Dr. Preston C. Coleman, Colorado (reelected); eighth district, Dr. Oscar S. McMullen, Victoria (reelected); seventh district, Dr. Joe C. Gilbert, Austin; ninth district, Dr. William B. Thorning, Houston, and tenth district, Dr. Murff F. Bledsoe, Port Arthur (reelected); delegates to the American Medical Association, Drs. John M. O'Farrell, Richmond, Edward H. Cary, Dallas, and Holman Taylor, Fort Worth, and alternates, Drs. Murff F. Bledsoe, Port Arthur, and Robert W. Knox, Houston.

WASHINGTON

Presented Forged Credentials.—A report from the state board of medical examiners recently stated that a Dr. Francis J. Koler was licensed on credentials showing that he graduated from the University of Minnesota, June 5, 1915, and that he had been licensed in Minnesota in the same year. These statements were not verified by official data at the headquarters of the American Medical Association and a letter from Dean Lyon of the University of Minnesota Medical School stated positively that no such person had ever graduated from that institution. Statements to this effect were at once forwarded to the Washington board. It is now reported that on May 28, Mr. Koler admitted that his diploma and the reciprocity blanks, together with seals of the university and state of Minnesota, had been forged. He agreed to return the license thus fraudulently obtained. He then left for parts unknown. Other licensing boards will do well to be on the lookout for Mr. Koler.

GENERAL

General Gorgas Honored.—The knight commandership of the Order of St. Michael and St. George was recently conferred on Gen. W. C. Gorgas by King George of England. Dr. Gorgas is en route to make studies of yellow fever on the west coast of Africa.

Limit Liquor Prescription Issue.—In an effort to defeat the indiscriminate sale of liquor on physicians' prescriptions, Commissioner Williams of the Bureau of Internal Revenue, issued a ruling, May 28, limiting the number of prescriptions for physicians to 100 for each three months, excepting with "good cause."

Sanitarians Hold Meeting.—At the annual meeting of the Southern Sanitary Association, held in Charlotte, May 25, Spartanburg, S. C., was selected as the next place of meeting and the following officers were elected: president, Dr. Andrew J. Warren, Charlotte, N. C.; vice presidents, Dr. C. C. Hudson, Richmond, Va., and Mrs. Ruth A. Dodd, Columbia, S. C., and secretary-treasurer, Dr. E. C. Smith, Columbia, S. C.

Virginia and District Meeting.—At the annual meeting of the Medical Society of Northern Virginia and District of Columbia held in Alexandria, Va., May 19, Dr. George Tully Vaughan, Washington, D. C., was elected president; Dr. Arthur Hooe, vice president; Dr. William H. Davis, Washington, D. C., recording secretary; Dr. Joseph D. Rogers, Washington, D. C., corresponding secretary, and Dr. Robert S. Lamb, Washington, D. C., treasurer.

Grants for Research.—The committee on grants of the American Association for the Advancement of Science has made a grant of \$100 to Prof. Theodore Hough of the University of Virginia, Charlottesville, in support of his studies with Dr. J. A. Wardell on blood changes after severe hemor-

rhages, and of \$150 to Prof. Carl J. Wiggers of Western Reserve University, Cleveland, in support of his investigations of the cardiac function by optical registration.

American Pediatric Society Elects.—The American Pediatric Society, at its thirty-second annual meeting held in Highland Park, Ill., May 31 to June 2, elected the following officers: president, Dr. John Howland, Baltimore; vice president, Dr. Charles A. Fife, Philadelphia; secretary, Dr. Howard Childs Carpenter, Philadelphia; treasurer, Dr. Charles Hunter Dunn, Boston, and recorder and editor, Dr. Oscar M. Schloss, New York City.

Fellowships Offered.—Four fellowships of \$1,200 each have been offered by Julius Rosenwald of Chicago to negro graduates for advanced medical studies. The fellowships thus far announced are Drs. George W. James, Jr., Howard University, 1918; Theodore K. Lawless, Northwestern University Medical School, 1919; W. S. Quinland, Meharry Medical College, 1919, Harvard Medical School, 1919-1920, and Carrie D. Sutton, Howard University, 1920.—A \$1,000 fellowship is offered by the Child Health Organization of America, New York City, for the best plan and outline for interesting children in the establishment of health habits.

Using the Automobile Emblem.—Hon. S. S. Horn, mayor of Easton, Pa., has addressed a letter to the members of the medical profession of that city urging them to mark their cars with the Caduceus so as to permit traffic officers to recognize physicians' cars. The mayor recognizes that many times a physician's car should be granted certain privileges which are not permitted except for fire apparatus and ambulances. Mr. Horn knows that it is impossible for a traffic officer to recognize every physician or know their cars. Consequently, he feels it would be of great advantage to have an emblem which will mark physicians' cars. He suggests the use of the automobile emblem provided by the American Medical Association for marking the cars of all legally qualified practitioners of medicine.

Warning Against Untried Medicaments.—The U. S. Public Health Service has issued a bureau circular regarding the use of arsenic preparations in the treatment of syphilis, in which it invites attention to the extensive exploitation through advertisements in professional journals and elsewhere, of various arsenic preparations which are not related to the arsphenamin group but which are sold with unwarranted claims as to their value in the treatment of syphilis. In the opinion of the bureau, the subcutaneous, intramuscular or intravenous use of arsenic in the treatment of syphilis should be confined to the arsphenamin group, as these agents are now of established value and are produced under the regulations of the Public Health Service. These agents are now manufactured by the following licensed firms: Dermatological Research Laboratories, 1720 Lombard Street, Philadelphia; H. A. Metz Laboratories, 122 Hudson Street, New York City; Diarsenol Company, Inc., Buffalo; Takamine Laboratory, Clifton, N. J., and the Lowy Laboratory, Newark, N. J. Provision is made for the experimental use of any preparation under conditions which will make the results of the experiment available to others than the physician immediately concerned.

Research Council Election.—The National Research Council, a cooperative organization of leading scientific and technical men of the country for the promotion of scientific research and the application and dissemination of scientific knowledge for the benefit of the national welfare, has elected the following officers for the year beginning July 1: chairman, H. A. Bumstead, professor of physics and director of the Sloane physical laboratory, Yale University; vice chairmen, C. D. Walcott, president of the National Academy of Sciences and secretary of the Smithsonian Institution; Gano Dunn, president of the J. G. White Engineering Corporation, New York, and R. A. Millikan, professor of physics, University of Chicago; permanent secretary, Vernon Kellogg, professor of biology, Stanford University, and treasurer, F. L. Ransome, treasurer of the National Academy of Sciences. The council was organized in 1916 under the auspices of the National Academy of Sciences to mobilize the scientific resources of America for work on war problems, and reorganized in 1918 by an executive order of the President on a permanent peace-time basis. Although cooperating with various government scientific bureaus it is not controlled or supported by the government. It has recently received an endowment of \$5,000,000 from the Carnegie Corporation, part of which is to be expended for the erection of a suitable building in Washington, D. C., for the joint use of the coun-

cil and the National Academy of Sciences. Other gifts have been made to it for the carrying out of specific scientific researches under its direction.

Status of Sheppard-Towner Maternity Bill.—A distinct step toward the passage of the Sheppard-Towner Maternity and Infancy Bill has been accomplished by the favorable report on this measure which has just been made to the Senate from the Committee on Public Health and National Quarantine. The bill provides for cooperation on the part of the national government with the several states in the care of maternity and infancy cases and provides for studies, investigations and reports thereon. It sets aside \$480,000 each year, of which \$10,000 is to be paid annually to each state for carrying out the provisions of the act. It creates the Federal Board of Maternal and Infant Hygiene for the purpose of administration of the law. This board shall consist of the Secretary of Labor, the chief of the Children's Bureau, the Surgeon-General of the Public Health Service and the commissioner of education. The bill appropriates the sum of \$2,000,000 for the next fiscal year in carrying on this cooperation work among the states and proposes appropriations for each succeeding year to 1925 in the sum of \$3,600,000. Before any state can secure the benefits of these appropriations, the legislature of such state is required to authorize the creation of a state board of mental and infant hygiene which will cooperate with the federal board. It is also provided that the cooperative work in promoting the care of maternity and infancy shall consist of instruction in the hygiene of maternity and infancy through public health nurses, consultation centers, and other suitable methods, and the provision of medical and nursing care for mothers and infants at home or at a hospital when necessary, especially in remote areas; and this work shall be carried on in such manner as may be mutually agreed on by the federal board and any state receiving the benefits of this act. The report of the committee in support of the bill was made by Senator France of Maryland. It says in part:

The testimony brought out that it is safer to be a mother in 14 important foreign countries than here in our own country. In 1918 23,000 mothers died from causes connected with childbirth and nearly a quarter of a million babies died under 1 year of age. Most of these deaths are preventable. It was further brought out that the protection of the child must begin with the protection of the mother. Care during pregnancy and confinement and instruction in the hygiene of maternity, infancy, and childhood must be made available for all mothers through such agencies as prenatal clinics, maternity hospitals, maternity care in the home, children's health centers, and systems of public health nursing adequate to reach every mother and child.

This neglect of maternity and infancy leads not only to thousands of preventable deaths but to lowered vitality and permanent impairment of health and efficiency for thousands of women and infants who survive. The Children's Bureau's studies in rural areas in six different States have revealed:

1. High maternal mortality rates, above the average for the United States as a whole.
2. The fact that 80 per cent. of the mothers had received no advice or trained care during pregnancy.
3. Many mothers had no trained attendants of any kind at confinement.
4. Inaccessibility and often entire lack of hospitals, doctors, and nurses.
5. Practically no organized effort to meet the need for instruction in prenatal and infant hygiene and for trained care during pregnancy and confinement.
6. An almost prohibitive cost for providing adequate care at confinement in scattered and isolated rural districts. The very districts where advice and supervision during pregnancy and better help at confinement are most needed are the ones least able to obtain it without financial aid.

Of more than 22,000 city babies studied by the Children's Bureau and representing every type of home in seven cities more than three-fifths were born into families where the fathers' earnings were below the amount which was at that time the minimum for providing the bare necessities of existence. Only 1 in 10 was in a family where the father's earnings reached a fair minimum for comfort.

The problem is not local or sectional, but nation-wide, and federal action, therefore, is urgently needed. This bill offers a practicable method of cooperation between the federal government and the states. Such a method is already successfully operating in promoting agricultural work, vocational education, and the building of good roads.

Testimony on file from governors of 33 states and mayors of many large cities indicates that the states are ready and eager to avail themselves of the provisions of this bill.

Medical experts testified that with the most ordinary nursing care given to mothers and the services of a nurse who will supervise and instruct the pregnant woman, the death rate in the first month of life can be reduced one-half or two-thirds. It has frequently been found that among babies of supervised women there is a death rate not exceeding 18 or 19 per cent., as contrasted with 40 per cent. of the babies of the women of the same class who are unsupervised.

Such care bears results immediately and almost with mathematical certainty, and there can be no question whatever that the women in rural communities should no longer bear the onus of having to con-

sider themselves outcasts, as it were, and not be able to avail themselves of the same kind of treatment that is at the service of certain city mothers.

Statistics have shown in New York City that, beginning five years after the commencement of work to reduce infant mortality, the effect was felt and the death rate under 5 years of age has been progressively lowered so that now the reduction in infant mortality is greater and the sickness rate is lower than it has ever been under 1 year of age. In other words, these children are not only saved to be alive at the end of the first year but are protected from physical defects, ill health, underdevelopment, and general physical deterioration in later life.

This bill equalizes the opportunities of mothers everywhere to receive suitable instruction in child hygiene in terms which they can understand, and provides for their care by those who are suitably trained. It also provides for methods of cooperation between various Government departments which have been dealing with certain phases of child welfare.

The representatives of Democratic and Republican women, and the League of Women Voters testified to the need of impressing upon lawmakers and politicians that the government has a responsibility for the care of mothers and babies. The greatest duty of government, the real purpose for which it exists, is to promote the general welfare.

Heretofore Congress has appropriated large sums for hogs and cattle. It is not because men think more of hogs and cattle than they do of babies that they vote \$47,000,000 for them and nothing for the little ones, but because they have been thinking of the father's end of the problem. They have not seen that there was another side to the problem that was just as much the public business, namely, right conditions surrounding mothers and babies at home. Mothers will always think of the baby first. They are made that way; that is why it is a good thing for women to be in politics at this particular stage of the world's history, when conservation of life is so important.

There is no difference of opinion among the women as to the necessity for this measure. Furthermore, they have great confidence in the administrative feature of this bill, which provides that it shall have as its administrative officer the Chief of the Children's Bureau. They feel strongly that this is a woman's question and they heartily approve of the legislation which proposes to give the administrative function of the bill to a woman, who is the Chief of the Children's Bureau and who has already done so much for the children of the Nation.

Other speakers testified that the death rates of babies within the United States vary from those which are exceedingly unfavorable, according to the care available for mother and child. Rural isolation, civic neglect, low income, ignorance, are among the chief accompaniments of high infant mortality in the United States.

Plainly, it is for the public interest that young life and maternal life should be conserved. But in order to give an approximately fair chance for life for every child born, it is impossible to rely solely upon local funds and initiative, otherwise the figures would not show the present extreme variations in localities of varying resources.

This bill recognizes that the family is the social unit, and that upon its physical, mental, and moral adequacy depends national progress. Family well-being involves many services, among them those of teacher, physician, nurse, and social economist.

The ground for this work is already broken in two-thirds of the states at least, the seed is already planted in the hearts of the executives, and only the stimulus of federal action is needed to make the work flourish.

It can not be ignored that the rising thought throughout the world recognizes that all life is precious, that life which is creating life is doubly precious, and that the mothers and infants must be protected.

This committee believes that Congress should take prompt action on this measure. It has been said that the 23,000 mothers who died from causes connected with childbirth in 1918 and the 250,000 infants comprised a total casualty list that is as large as our total casualty list during the war.

Congress should not be passive in the face of this great loss, not only economic but social and moral as well. We believe that the United States should be pulled up from its present ignominious position as a squanderer of mothers and babies.

CANADA

Personal.—Dr. Richard J. Harding, McGill University, has been appointed professor of chemical pathology in the University of Toronto by the board of governors of the university.—Dr. Daniel Murray has been reelected mayor of Campbellton, N. B.—Dr. William G. Anglin, Kingston, has been appointed surgeon to the provincial penitentiary, Portsmouth.

Alumnae Meet.—The annual meeting of the Women Medical Alumnae of Queens Medical College was held in Toronto, and the following officers were elected: honorary president, Dr. Augusta Stowe Bullen; president, Dr. Katherine Woodhouse; vice presidents, Drs. Isabella Smith Wood, Annie Saeveth Higbee, Grand Prairie, Alta., and Dorothea A. Orr, Toronto; secretary, Dr. Edna Robertson, and treasurer, Dr. Edna M. G. Guest, Toronto.

LATIN AMERICA

Children's Outing Station in Argentina.—The Buenos Aires municipal authorities have opened a vacation colony for the sickly children of the city.

Government Sanatoriums in Santo Domingo.—The government of Santo Domingo has begun the necessary steps for the construction of a number of sanatoriums in different parts of the country.

Public Health Appropriation in Paraguay.—The appropriation for public health purposes, granted by the last congress of Paraguay, amounts to 600,000 pesos, including the funds for the new services for the control of leprosy, hookworm, plague, tetanus neonatorum, etc.

Bubonic Plague in Mexico.—It is reported that all traffic by rail or steamship to Vera Cruz, with the exception of that over the railway to Jalapa, has been ordered suspended on account of the presence of bubonic plague in Vera Cruz. Major A. R. Goodman, M. C., U. S. Army, attached to the American embassy at Mexico, announced, June 5, that the situation is not so serious as the reports state and that the Mexican medical authorities are handling the situation efficiently and taking every precaution to prevent the plague from spreading to other parts of the country. According to the latest reports from Vera Cruz the number of cases of bubonic plague so far discovered in that city is twelve, several persons having already died. No new cases have occurred lately. The authorities have accepted the offer of the United States government to send a sanitary detachment to assist in combating the disease. It is reported that the outbreak is now under control.

FOREIGN

Donations from Norway to Vienna Physicians.—Dr. R. Nadwig arrived recently in Vienna conveying six freight cars loaded with edibles of a value estimated at 5,000,000 crowns, for Vienna physicians and their families, donated by the physicians of Norway.

Nurses Get Florence Nightingale Medals.—Fifteen nurses representing fifteen countries have been awarded the Florence Nightingale medal for heroism on the battlefield by the Geneva Red Cross. Among those who received the decoration were six American, eight British and eight French nurses.

Personal.—Prof. Sadao Yoshida of Osaka Medical College, Japan, who has been spending his sabbatical year in research work at the parasitologic laboratory of the University of Illinois, has been awarded the Katsurada prize and medal of honor established by the Japanese government to be given periodically to some distinguished workers on tropical diseases.

Portrait of Sir Clifford Allbutt.—The catalogue of the exhibition of the Royal Academy this year includes a portrait of Sir Clifford Allbutt, painted by Sir William Orpen and presented to Sir Clifford by the medical profession. The picture bears the inscription: "Sir Clifford Allbutt, K.C.B., M.D., F.R.S., regius professor of physics in the University of Cambridge, President of the British Medical Association, presented to him by his Profession in 1920."

Typhus in Poland.—Dr. Rupert Blue, formerly Surgeon-General, U. S. Public Health Service, who is in Europe investigating health conditions, has cabled Washington, D. C., for five additional surgeons to be sent to northern ports to inspect all third class passengers for America in view of the prevalence of typhus fever and cholera in Poland. It is required that all third class passengers be bathed and disinfected and held for twelve days at the port of embarkation.

Belgian Society of Psychiatry.—The Société de médecine mentale de Belgique will hold a jubilee congress in celebration of its fiftieth anniversary in Ghent, September 25-26. Dr. Ley, professor of psychiatry at the University of Brussels, is president of the congress, and Dr. Hovrey, Liebreux, Belgium, is secretary. Representative delegates from related societies of the United States will be accorded a warm welcome.
